EXTRACT

From an Act prescribing Rules for the Government of the State Library, passed March 8th, 1861.

SECTION 11. The Librarian shall cause to be kept a register of all books issued and returned; and all books taken by the members of the Legislature, or its officers, shall be returned at the close of the session. If any person injure or fail to return any book taken from the Library, he shall forfeit and pay to the Librarian, for the benefit of the Library, three times the value thereof; and before the Controller shall issue his warrant in favor of any member or officer of the Legislature, or of this State, for his per diem, allowance, or salary, he shall be satisfied that such member or officer has returned all books taken out of the Library by him, and has settled all accounts for injuring such books or otherwise.

SEC. 13. Books may be taken from the Library by the members of the Legislature and its officers during the session of the same, and at any time by the Governor and the officers of the Executive Department of this State, who are required to keep their offices at the seat of government, the Justices of the Supreme Court, the Attorney-General, and the Trustees of the Library.

SAN FRANCISCO, SATURDAY, JULY 1, 1876.

VOLUME XXXIII Number 1.

The Centennial Fourth.

The grestest day of all this greatest year is at hand and before another Passs shall have passed from us to yon, kind readers, the Centennial Fourth will have been hailed with rejoicing and celebration such as no day hss known since the first century of the republic began. While we ara now liugering on the verge of this peerless national rejoicing, let us instance a few thoughts which it is fittiug to remember,

What have we done iu a hundred yssrs? In the first plsce we have shown to the world the possibiliiy of a popular government. A people haa proved its right and ability to govern itself. We have triumphed over dissensions which would have wrecked most other governments, or else have placed one-half their people iu boudage. We have triumphed in such a way that there is neither victor nor vanquished, and our whole people are free, equal and fraternal to-day, as in the early happy days Where in the history of the world has there beeu snch a victory; where has war beeu so completely conquered?

Think for a moment of onr national growth One hnndred years sgo two and one-half millions of people rejoicsd ovsr the adoption of the Declaration of Independence; to-day, more than forty millions rejoice with full hearts and loud voice and declare again and again the brave words of the fathers of the republic. Theu there were 13 weak but hopeful colonies; now there are 37 strong and united States. Then the popular domain hugged the Atlantic shore, now it extends from ocean to ocean, snd the Pacific will sonnd a loud refrain to the rejoicings along the Eastern coast.

Nor has the growth of the oountry been in numbers alone. There has been a material prosperity keeping pace with the increase of population. The seed of liberty was planted on fruitful soil. The temple o. freedom and equal rights was erected in a land so rich in varied resources that its votaries were not nourished npon an idea alone, hut were led hy their own industry into the enjoymsnt of unequaled prosperity. The freedom to act, coupled with the materlal to act upon, hss won for us men from every clime, and the good land holds a good people. It is history as well as poetry which says to our country:

> "There's freedom at thy gates, and rest
> For earth's down-trodden and oppresst,
> A shelter for the hunted head,
> For the starved laborer t.il and bread."

The century which ranks first in our national history has no peer in the general advancement of mankind. No century has witnessed such grand indostrial achievements. In no century have bright thoghts turned so many powers and forces of nature to the service oi mankind. Never hefore has mechsnism lifted so great a weight from the hurden of muscle. What a tide of progress is called to mind by the mention of the single word—steam. During the centnry its greatest deeds have all been accomplished. The locomotive snorting upon mountain tops; the steamship cutting the waves and wind; the powerful stationary engine, locking in a narrow cylindsr the force of thousands of horses; all these are within the circle of the century. By the power of steam, miles have come to be counted in minutes; hnt this is only a trifling with time. The speed of intelligence waits not for such tardy csrriage. Over the mountains, across the plains, mounting the hills and threading the valleys of the East, plunging into the Atlantic, springing thence beyond the water, flying across the many kingdoms of Europe and laughing at the width of Asia, a thought from the Pac fic coast rings in the ears of the listener in China, almost before the lagging pencil can mark ont its course. Thie ie an every-day occurrence. We tbink no more of it than we do of the flash of a ray of sunlight, and yet it is wonderful beyond history, wonderful beyond even the imsginings of the fathers of the centnry. With such results accomplished through American invention and discovery, what less than prophecy do these words of Timothy Dwight, written at the heginning of the century, become:

> "Fair science her gates to thy sons shall nnbar,
> And the East see thy morn hide the beams of her star;
> New hards and new sages unrivaled shall soar,
> To fame unextinguished when time is no more."

To write the achievements of the first 100 years of the republic is really to write its history, for each period has some new and striking thought or deed. Thus has arrived the wonderful advancement of the country and the people. Progress has been continuous. The achievements of the past will serve to guide and impel the hand which will accomplish the deeds of progress which still lie before.

If it sfford satisfaction to review onr msterial progress, not less can he gained from the contemplation of our advancement in that which ministers to mental and morsl growth. Witnees our schoolhonses springing up every where close upon the heels of the pioneer; witness our higher schools and universities; witnese our vigorous youth in literature. No longer can the sneering foreigner ask "who reade an American hook?" for American hooke are covered with gold in Europe, and American authors are crowned with titulary honors hy the ancient universities of the old world. Intelligence presses home upon the dweller in this country upon the face of 5,000 newspapers; the refining and elevating influence of morality and religion descend from tens of thousands of pulpits; the spread of an enlightened public sentiment make right honorable and wrong perilous, throughout the length and breadth of the country. It cannot he denied that our good name muet he shown upon the background of some of the most villainous transactions known to history. The corruption which has been shown in high places has brought a blush to the face of the nation, hnt the condemnation which the wrong-doers have received shows that the national heart is right and the national conscience quick and active.

With just pride in the psst and with full confidence in the future, the people of the United States enter upon the second century of the nation's life. We are at peace with all the world. The time is propitious for still further progress along the line of advancement which we have heen pursuing. There is still much to be done in the way of promoting the prosperity of eome large classee of our population. In the rapid progrees of the last few yeare there have arisen some pernicious growthe. Powers have been confided to the few which helong to the many. Self interest has plumed itself under the guise of the general welfare and is still permitted to exalt itself even to the oppreesion of the many. It ie to the removal of these obstacles to true progress, and to place privileges and powers where they justly helong that the work of the future must he addreesed. Tbere are indications that thie work is now under way. The grand industrial classes of our population are advancing in mutual knowledge and in the intelligence which pertsins to their sncress. The future is full of promise that the great masses of our people will secure those reforms which their prosperity demands, and that their voice will he more clearly heard and more generally respected in the halls whence coms the laws. It is the advanca of right, and its progress is most hopeful for the republic. The end is sure, for

> "The eternal step of progress heats
> To that great anthem, calm and slow,
> Which God repeats."

Centennial Bells.

Ye belfry'd blacksmiths in the air,
Smite your sweet anvils good and strong!
Ye lions in your lofty lair,
Roar out from tower to tower, along
The wrinkled coasts and scalloped seas,
Till winter meets the orange breeze
From bridal lands that always wear
The orange blossoms round their hair.
Centennial Bells, ring on!

Pour ont, ye goblets, far and near,
Your grand melodious Iron flood,
Till pine and palm shall think they hear
The axes smite the stately wood,
Nor dream the measured cadence msant
The clock-tick of the continent!
The fo t-fall of a world that nears
The field-day of a hundred years.
Centennial Bells, ring on!

Ye blossoms of the furnace fires,
Ye Iron tulips rock and swing,
The People's Primal Age expires,
A hundred years the reigning king.
Strike one, ye hammers overhead,
Ye rusty tongues, ring off the red,
Ring up the Concord Minute Men,
Ring out old Putman's wolf again.
Centennial Bells, ring on!

Where prairies hold their flowery breath
Like statues in the marble ledge,
Where mountains set their glittering teeth
Through blue horizon's rugged edge,
And hold the world with granite grip
As steady as a marble lip.
And here, and there and everywhere,
With rhythmic thunder strike the air.
Centennial Bells, ring on!

Ring down the curtain on To-day
And give the Past the right of way,
Till fields of battle red with rust,
Shine through the ashes and the dust
Across the Age, and burn as plain
As glowing Mars through window pane.
How grandly loom like grenadiers
These heroes with their hundred years!
Centennial Bells, ring on!

Ring for the blue-eyed errand boy
That quavered up the belfry stair,
"They've signed it! Signed it!" and the joy
Rolled forth as rolls the Delaware.
The old man started from a dream,
His white hair blew, a silvery stream,
Above his head the bell unswung
Dumb as a morning glory hung;
The time had come awkited long,
His wrinkled hand grew young and strong,
He grasped the rope as men that drown
Clutch at the life-line drifting down.
The Iron dome as wildly flung
As if Alaska's winds had rung.

Strange that the founder never knew,
When from the molten glow he drew
That bell, he hid within its rim
An anthem and a birthday hymn.

So rashly rung, so madly tossed,
Its old melodious volume lost,
Its thrilled horizon rent and cleft,
Of sweet vibration all hereft.
And yet, to hear that tocsin break
The silence of a hundred years,
Its rude discordant murmurs shake
And rally out the soul in cheers
Would set me looging to be rid
Of sweeter voices, and to bid
Centennial Bells he dumb!

Although no mighty Muscovite,
No Iron welkin rudely hurled,
That hell of Liberty and Right
Was heard around the Babel world!
Land of the green and golden robe!
A three-hours' journey for the sun,
Two oceans kiss thee round the globe,
Up the steep world thy rivers run
From geologic ice to June.
A hundred years from night to noon!
In blossom still, like Aaron's rod?
The clocks are on the stroke of one,
One land, one tongue, one Flag, one God!
Centennial Bells ring on!

—*Ben. F. Taylor in Scribner's.*

Operating Hydraulic Nozzles.

Henry C. Perkins, of North Bloomfield, Nevada county, has recently patented through the Mining and Scientific Press Patent Agency a method of moving the discharge nozzle of hydraulic mschines from side to side, or so as to point in any desired direction. He accomplishes this by means of the dsflecting power of the stream from the nozzle itself, through the intervention of suitable plates.

The ordinary discharge pipe of a hydraulic machiue, such as is nsed for washing down gravel banks, is used. These nozzles are usually of large diameter and water is bronght to them nnder great pressure, so that it is very difficult to move the nniversal joint with which they are constructed, and many devices comprising powerful levers have been used for tha purnose.

Mr. Perkins has found, however, that by suitably manipulated tnhes, plates or rifles, the force of the stream issuing from the nozzle may be made to tnrn the pipe in any direction without the nse of any other device. For instance, a short section of tnhe is taken, which msy he somewhat larger than the nozzla; that is, if the nozzle is six inches in diameter, the interior diameter of the tnhe msy be seven inches, so that when mounted upon the pipe, jnst beyond or about the end of the nozzle. tha stream of water will pass through it without touching, hut if the tnhe be turned to either side, the force of the watsr acting against the side will cause the whole nozzle to move in that direction.

In order to mount the tnhe so as to move it readily in any direction, it is secured to one arm of a lever, while the other arm extends back along the line of the pipe. The fulorum of the lever is snpported upon a swivel joint which is capahle of heing turned in sny direction. This joint is snpported from helow from a ring snrrounding the nozzle, or gimhals may he fitted to support the deflecting nozzle. It will readily be seen that distinct deflecting plates might he snhstituted for the nozzle or tnhe or in some cases a rifle or plate might he mounted like a butterfly valve upon an arm passing through the side of the nozzle near its end, so as to stand in the stream, and hy turning the plate from side to side the desired effect might he produced. A rest serves to support the lever, and retain the deflector in a straight line when not in nse. By this means the prinoipal mschinery needed to operate these larga nozzles is done away with, and the labor is reduced so that a child could manage the largest machine.

The National Gold Bank and Trust Company have resumed general hanking husiness on tha northwest corner of California and Montgomery streets, in the rooms lately occupied by Wells, Fargo & Co.'s hank. The Trust Company hnilt up a splendid husiness hy affording proper and safe accommodations to the public. Unfortunately for the hank, (hut luckily for some others,) they received the hrunt of the panic after the failure of the Bank of California, and had to euspend, which they did in an honorahle manner, paying dollar for dollar, and still having a surplns. The company now has the respect and confidence of a host of good citizens, and they may confidently anticipate a prosperous and rising hueiness.

Connection Made.—The connection hetween the C. & C. Shaft and the California and Consolidated Virginia mines was made on the 24th inst. This is another outlet formed from the 1500-foot level of the honanza mines—a grand highway it might he called.

CORRESPONDENCE.

Some of the Mines of El Dorado County.

[By our own Correspondent.—No. 5.]

My correspondence in regard to mines in El Dorsdo county is sgain resumed somewhat abruptly.

The Original Blue Lead,

Near Spanish flat, owned in part hy Mr. Varozza, the accommodating landlord of the Cary house, Plecerville, wss visited for his sake, end the prospects were fonnd trnly enconraging. The lode is from three to four feet in width. Ore on dump looks as well es any I have seen in this county at the same depth. It is thought in the neighhorhood to he a fine mine, and that the ore will run anywhere from $10 to $80 per ton.

The St. Lawrence,

Kelsey district, is looked upon as one of the best mines in this country, es it for a long time paid handsome dividends. Preparations for opening np the mine anew sre going forward energetically nnder the management of Mr. H. Rosewarn, the new superintendent, a miner of much prsctical experience, snd hright anticipations are cherished here for the fnture prospects of this vicinity when the water is once lowered to the 800-foot level. The ore averaged about $22 per too, and it is said that the last taken out was the hest, being adjudged $30 ore. They have a 30-stamp mill, 14-inch engine, 12-inch hoistiug engine. They use one of the Wilcox pumps, which gives entire sstiefaction. Have a saw mill also, which proves itself very useful end conveuient.

The Mansfield,

One mile from the last, has heen opened hy two tunuels, one of 213 feet and auother of 230 feet, together with side drifts aggregating 230 feet. They are tunuing for two ledges, one of which is of a somewhat peculiar formation, some 17 fest in width. The mechiuery is said to he all iu good working order. Was informed by the superintendent thet the sinking of the new shaft was going on at the rate of three feet per day, with intention of driving it to the depth of 200 feet.

Iu thie connection may he meutioued a heautiful lode of fine looking ore just beiug opened here, called the Gold Deposit, hy Mr. J. L. Smith, who, by the way, is oue of the pioneer miners on this coast. The prospect looks flattering.

The Rosecrans,

Near Garden valley, is opened hy shaft, or rather incline, 18x6 feet, following the lode to the depth of ahont 70 feet. This mine has paid wonderfully in view of all the disadvantages under which it has lsbored. The lode is from four to six feet in width. The rock teken out in sinkiug incline was saved and crushed, amounting to about $6,000. There is a five-stamp mill conveniently situated to the mine, and all the arrangements have heen mede to put on a steam pump for raising the water, which will greatly fecilitate the operations. This mine hids fair to he one of a permanent character, the ore heing similar to that of its next adjoining neighhor,

The Taylor.

Yon have alreedy learned, perhaps, that the entire machinery of the Cedarherg mine, including a 10-stamp mill, hoisting works, air compressor and Burleigh drill, have heen purchased and transferred here, giving the company 20 stamps altogether. They have a shaft 400 feet and have commenced to sink enother 100 feet to open up another level. They strock a rich pay chute at the 100-foot level which was about 40 feet in length. At 200 feet it was 50 feet, and st the depth of 400 feet it lengthened to the distance of 260 feet, where the vein is fonnd to he about 13 feet in width. It shows throughout free gold and rich sulphnrets. Thie mine, like the Rosecrans, last described, on the same lode, is helieved to stand on a solid and substantial hasis, end to have opening up for it a hright futnre.

The Woodside Mine,

At Georgetown, hae a good prospecting mill of five stamps, and machinery of all kinds of the very h st qnality. The present sheft is 250 feet, hut off the line of the vein.

The oompeny are now sinking an incline from the foot of the shaft to follow the ledge down thr ugh a rich pay chute, which has paid as high as $40 per ton. $5,000 were taken out of this chimney within oue mouth's run. Mr. Gibbs, the superintendeut, showed me his mode of saving and reducing his sulphurets, which is so simple and effective as to call for a little descripuon in detail, end worthy the st-tention of mill-men. For saving the sulphurets a common rocker is kept in motion hy a helt connecting with the machinery, making about 30 oscillations per minute, and the grade of rocker beiog about four inches in 12 feet. The sulphnrets, after heiug thoroughly ioixed with sawdust, and with the addition of about five pounds of common tahle salt to the ton, are placed in a small furnace to he roasted. The sawdust helps to start the fire end the sulphur keeps it a-going. The sulphurets are hrought to a sufficient heat simply to destroy the sulphur, a greater heat not heing desirahle. A shovel-full is put into the furnace et a time snd the seme amount tsken from heneath the grate to ooe of Knox's grinding pans, where sufficient quicksilver has heen pleced to collect the gold. One men cen attend to the whole process.

The mines at Volcanoville, Georgia Slide end Greenwood will prohably demand another lettor from this county.

At Volcanoville,

Work was going forward in the way of developing two quartz mines, snd also on two large gravel claims, hesides a considerahle amount of mining hy drift and sluice, some of which is of sofficient importance to he noticed in detail.

The Oore Mine,

Belonging to one of your prominent real estate citizens, has heen worked for the past yesr; lode from three to six feet, somewhst hroken up near the surface, hut hecoming more defined es opened. A tunnel has heen run in immediately ahove the mill, connecting with an incline 65 feet, which has followed the ore down to the point of connection. Mr. E. Rodecker, the superintendent, informed me that some of the sulphnrets taken out near the surfece were almost three-fonrths gold, hy actual test on a small scale. If they could only he found in quentity, the great value of this mine could not he questioned. The ore, so far as milled, rons from five dollars to ten dollars per ton. It is said that with all the conveniences in the way of wood and water and facilities for getting the ore from mine to mill, five dollar rock onght to pay well. The capacity of the 10-stamp steam mill is about eight or ten tons for every 10 hours.

The Volcano Ledge and Mining Company

Heve located 1,500 feet south of the ledge, which has heen opened hy a shaft and drift from the bottom of it, cutting the vein at a depth of 50 feet from the surface. The lode, from foot to hanging wall, is ahout 14 feet; vein matter eight or nine feet. The company are now piping off the surface in order to expose the vein, and ere making good wsges. It is owned hy the Graves Brothers, superior miners from Grass Valley, who are fully persuaded that this is a hetter point for successful quartz mining than the former place. Mr. A. Graves furnished me with a fact thet had come under hie observation, which sesms worthy of heing published for further confirmation. It may he local in character and not of general application: Where a cross course comes in and the ledge is lost, from heing thrown out of its usual direction, it is invariably found again from 10 to 100 fest, hy drifting always to the left from the point where it ceases, and never on the right hand. If a fact, let the scientist give the canse.

The Volcanoville ridge has a generel elevation above the Middle fork of the American river of ahout 1,500 feet, and a heavy gravel deposit of from 25 to 300 feet in depth, and six or seven miles in length, the average hreadth heing nearly a mile. The mines tail on the north into the river, and on the south into Otter creek.

The Mount Hope Gravel Claim,

The property of the California water company, has a hank 230 feet high, the whole of which pays for washing and some strata exceedingly well. They have water during the whole season, using ahout 1,000 inches; pressure 300 feet; number four gient, latest patent, and tunnel flume three feet in width.

There are any amount of falls or dumps from 20 to 30 feet in hight, numerons inclines, and one fall of at leest 150 fest. It is a sight worth seeing to look into the flumes and see large rocks gliding swiftly down them, leaping from fall to fall, flying with lightning speed down incline after incline, then hurled as from a catapult to the foot of the largest fall, to he shattered amid dashing spay and sounds of thunder into ten thousand fragments on the crags below.

The useful and the heautiful in art and natnre are here combined to adminieter to the wants of man.

The Mt. Gregory Water and Mining Co.

Have 1,000 acres of mining ground on this same ridge, aud are at this time running one hydraulic claim. Their bank of gravel is from 80 to 100 feet high, most of it of a heavy quertz character, similar to that at Michigan Bluff, some of the largest houlders heing found here that have heen met with anywhere. Both fine and coarse gold is fonnd; sometimes a piece worth $50. Occasionally a little quertz gold has heen picked up. The average yield per cubic yerd so far as worked about 20 cents.

As in the former claim, ahout 1,000 inches of water is used at this time. They have one little giant, numher five, six-inch nozzle, 250 feet pressure, pipe 22 inches and 16 inches in diameter. The derrick is run hy a hurdy-gurdy wheel, and they have ell the fall required, in the direction of Otter creek. These two companies have ground that must he exceedingly valuable and conld not he hetter situated for working to good advantage, and are the hest gravel claims heing at present worked between the South and Middle forks of the American river. There is, however, a very large amount of similar ground here which will give out its gold for many years to come.

On the river below Volcanoville, work has hsen commenced on a new enterprise which, if carried out in accordance with the programme, will he an immense undertaking.

The Oliver Mining Company

Have secured in the counties of Placer aod El Dorado 78 claims of 1,500 foot each. They have a 100-foot lode, with greenstone slete for foot wall end serpentine on the east or hanging well. Two tunnels will he started from the river, one running north and the other sonth along the veio, with the view of securing hetter drainage and avoiding the great expense of sinking and hoisting. It will attain prohahly a depth from the surfece on the line of lode of 2,500 feet.

Ooe of the Cowles patent giant quartz mills is in process of erection with the view of working the vein matter, five tons of which, owing to its peculiar character, can hs crushed as cheaply and as easily as one of qusrtz

Spar, talc and porphyry streaked with ashestos are the principal components. A similar formetion was passed near Spanish Flat, which is said to he paying well for washing. The so-called sospstone mine (Buckeye claim) near Kelsey, is substantially of the same nature. If the theory of Mr. Oliver, the superintendent, is true, Volcan'e old forge was of the same material. As his hypothesis is hoth novel and originel, a little morsel hy way of dessert will he now served up. He helieves that this vein matter is the trne matrix of gold instead of quartz es generally received, the latter hsing only a receptacle, as auy other kind of matter might he if the gold came in contact with it hefore cooling after heing brought up from helow in the form of super-heated steem.

As this material makes a good fire proof clay, he thinks it almost self-evident that it has heen subjected to the greatest possible amouut of heet, and has heen thrown up from the vicinity of the great metalliferons store-house at the same time with the gold, and hy means of the same forces; quertz, on the contrary, has bsen formed from above downwards, and the fissures gradually filled during the process of cooling.

The gold in the Oliver is represented as very free, amalgameting readily and running about $17 per ounce, while assays of vein give en average result of one-half silver. The ore will first he worked for the gold, the sulphnrets concentrated, and afterwards reduced hy the silver process.

A Dividend Paying Mine.

The Sliger quartz mine is sitnated not far from Spanish dry diggings, in one direction, and from three to four miles northerly from Greenwood. The width of the lode at the present dspth is ahout 14 feet, hut ths psy ore is confined within the limits of ahout six inches, and extending along the foot wall. The last crnshing of 41 tons peid at the rate of $40 per tou. We were shown some hsautiful specimeus here, which hring ahout $40 per ounce, heing easily disposed of to lapidaries. Sometimes a single hlast has thrown out $5,000. This mine has heen worked for the past four yeers hy the present company, and a dividend of $5,000 has heen declared to the share (four full shares); snd hefore this notice appeers another dividend will have hsen made to the shareholdere of $7,000 more. They have a five-stamp water mill, all in good order. Economy is one of the mottoes, evidently, in the general working of the mine, which accounts in great pert for its success.

The north extension of the Cedarhurg, lying south of the Sliger and nearer Greenwood, is at present engeged io sluiciog down the hank near their lode. Meny rich and heautiful quartz specimens are found from day to day, worth from $5 to $100, and supposed to have h en hroken from their hest vein, which may he laid hare at almost any moment. One piece of over $1,000 was picked up not long since, and another some months ago, valued at $5,000.

The International Gold Mining Company

Comes next in order as you approach Greenwood, running for the same ledge as the Sliger and nortbeast of Cedarhurg. Has tunnel 275 feet, and another 67 feet lower 400 feet in length, connecting hy shaft with the upper works. Several drifts have heen run. In the main south drift from the lower tunnel some very rich sulphurets have heen found; average assays $200 per ton, some as high as $4,000. Small veins of quartz have heen encountered, which are evidently feeders pointing to the ledge. One seem has heen followed for the lest three weeks, that contains gold and specimens similar to those referred to in the last described claims, snd enough to pay the expenses of running. The work is now heing pushed under the superintendence of Mr. John Tuttle hy night and day, with the expectation of reachiog the main ledge within a run of 40 feet or more.

Before closing report of mines in this county a few cases of seem claime will he noticed. These are most numerous at Georgia Slide, Spanish dry diggings and at Greenwood. Where they are very small it does not pay to pass the quartz and dirt through the mill, although more gold could he taken from the claims than hy hydraulic. It would require too much time and labor. In this case the whole hank is pip d and sluiced.

On the Parsons claim, at Georgia Slide, some of the veins are from four inches to two feet in thickness. Here they have a mill end save the quartz for crushing, after having previously laid their lodes hare by a vigorous use of the hydraulic.

There are here in one place two veins not many feet epart, one with an eastern dip and the other a western, as if they would soon unite. Immediately over the hest pay ore there were a large number of smaller veins, branching off in different directions from the main lode and in all kinds of lines, direct, circular and more or lese angular, in very hard rock, indicating an enormone force at that point, leading one to think the ceuse of the rich chute might hear some relation to the facts here set forth. Mr. Hsneon, who has heen for a long time working this clsim, had come to the same conclusioo, snd pointed ont in other portions of the mioe similar indications, where he expected to fiod good paying chimneys. He is now sinking an incline on one of these, which he usually finds to pitoh north in the direction of the lode at an angle of ahout 45 degrees.

The old Taylor claim at Spsnish dry diggings is paying from six to ten onnces per week; six men employed. The Short Handle and Horse Power (Sites & Co.) paid well et one time, four men having taken out as much as $40,000 in three weeks. It is at present worked hy slnice, and is mekiug fair wages, hut as it lies flat machinery is required to work it with advantage.

The Pennsylvania, owned hy Mr. L. Sites, is 600 feet in length hy 400 in width, and is admirably sitoated for working hy slnice in wioter or hy hedrock tnnnel in summer. As Mr. S. was an old acquaintance, I was favored with some figures in regard to this claim which sre not generally known among hie neighhors. He had juet deposited 28 onnces which he had weshsd out with the aid of one man in seven or eight days. He frequently gets $50 and sometimes as high as $200 to the pen. This claim has paid him $10 per day since January last, or about 125 ounces, worth $17.50, during a period of five months. K.

Overland Chat.

[For the PRESS by MARY MOUNTAIN.]

No one cen fully realize the desolate ssmeness of Nevada scenery until they travel through and spy out the land.

Reno in the cool, clear air of morning had a brisk and husiness look with its clean, new houses and faces of

"Consolidated" Keenness,

And in several other little towns the homes looked as homelike ss is possihle with euch hleak surroundings; hut our pilgrims seemed to think it would he wild catty iodeed to take stock in the soil or visible productions of this famous country.

All along here our San Francisco stock hrokers hroke out in such eager excited talk oue might imagine them sniffing very olosely the richness of hidden treasure. The wife of oue of these was a friendly, chatty little hody, and told me they would have gone to see the old mother long ago if it had not heeu that

"Stocks Acted So Mean;"

And much of her Centennial pleasnre depends upon stocks hehaving as they ars expected to. I admired the good sense that had led her to trevel in a neat derk calico; and the skill of her cookery, toasting, hoiling and hroiling over the queer car stove was truly wonderful. When we reached Omaha this chrysalis became a huttsrfly and hardly a lady in San Francisco could excel her in richness of garments end jewelry.

At Ogden we hranched off to

Salt Lake City,

Accompanied hy the Germen professor and our little echool-me'am. We had hy this time a good right to say "our school-ma'am" for she was traveling alone and glad to he gathered under our wing.

Of course the Professor's little children were along, and a pleasure to heve them; for they are intelligent, petient and polite. Little Otto, the youngest, had heen homesick the day hefore and asked "Where, then, ie onr home, pepa?" The answer was, "Here, my child, in the seat with papa." So he tried to accept it and hegan to ask the other children to visit his home. How glad we were to leave those close homes and prance away to the heautiful valley with plenty of room! And now egein my adjectives hegin to weaken, for this valley and city and grand snrrounding chain of snow-capped mountains form together the most heautiful right I have ever seen.

Doubtless the ewift change from the ugliness of

The Alkali Desert

Tends to highten the charms of this perfect oasis that is now set in our memories as a joy forever.

The valley is larger, the city handsomer, the mountains whiter with enow and more complete in circle than I had expected, for they reach an arm along the northern houndary to keep off cold winds and nestle this darling nook in a climate full of health and sweetness.

As we ascend a terrace of the town the eye takes in the whole area of 20 miles wide, 25 miles loug, end close in the foreground are the houses of Brigham, the broad, low dome of the tahernacle, the temple slowly growing into a thing of heauty, and ah, "the whole city full" of pleasaut homes and neat, quiet streets.

The high-walled gardens are filled with froit trees, vegetahles, and a gay trimming of flowers and little white-headed children peeping through the getes.

If I say that the public buildings are handsome, the smoke of manufacturiog like a cloud in the distance, the Great Salt lake shining and still nnder the far off mountains, let no

(Continued on Page 6.)

MECHANICAL PROGRESS.

The Whitby Jet Manufacture.

The manufacture of jet ornaments has constituted the staple industry of Whitby, England, during the present century, but its most notable development may be said to date from the great exhibition of 1851. On that occasion the little Yorkshire seaport brought its distinctive trade into prominence for the first time, and the demand for its productions received a stimulus which has been renewed at subsequent world's shows. The growth of the trade may be judged when it is stated that in 1850 there were but 50 workshops in the town, while at the present time Whitby can boast of nearly five times that number, the annual value of the trade approximating to £100,000. The largest manufacturing concern is that of Messrs. Chas. Bryan & Co., in Wellclose square, the head of which is to be credited perhaps in a greater degree than any other person with furthering the development of the trade, both in its industrial and commercial aspects.

Jet is so admirably adapted as a material for mourning ornaments that we are quite prepared to hear that the productions of Whitby find acceptance in all parts of the world. That this peculiar industry should have centered itself in that town is due to the accidental fact of large deposits of the raw material existing in the cliffs of the neighborhood. These have been drawn upon to such an extent, however, as to compel the jet miners to open up other sources of supply. At the present time the greater portion of the jet worked up in Whitby is excavated from the hills of the Cleveland district, some eighteen miles inland.

What Is Jet?

There is some difference of opinion as to its exact nature. It has been regarded by certain geologists as petrified wood, that is to say, a description of coal, which it resembles somewhat closely in composition. Others incline to the belief that it is of animal origin, this supposition being based on the fact that bones have been found with their exterior converted into jet. It may safely be set down, however, as a bituminous mineral, and it appears probable that the fluid exudations of what is called the jet rock have impregnated both animal and vegetable substances, thus giving rise to the remarkable specimens of jet occasionally found. The jet deposits are found lying horizontally in the upper lias or alum shale, which formation fringes the Yorkshire coast for more than twenty miles. Two kinds of jet are recognized—the hard and the soft. The former is most highly esteemed, and is worth about 21s. per lb. It is not harder than ordinary coal, but is capable of being easily cut and carved, and of receiving a very beautiful polish. Spanish jet is imported to some extent, but is very inferior to the Whitby variety; that found in France is accounted worthless by our manufacturers, and is little used.—*British Trade Journal.*

HE VALUED HIS MACHINE HIGHER THAN HIS TITLE.—The late Baron Palm, of New York, when he came to this country brought with him a patent machine for pressing bricks, which he valued more highly than he did his patent of nobility. But before he became known as a brick-maker, he was much sought after by the leaders of fashion on the score of his being a real Austrian baron. The high priest of the Theosophists, Col. Olcott, in his address over the remains of his departed friend and disciple, said that his ancestors had been barons for a thousand years, but Baron Palm did not pride himself so much upon his descent from so long a line of ruffians and robbers, as he did upon his mechanical invention, which, he flattered himself, would be a better recommendation in our Republican society. But he was soon disillusioned. He had been introduced to a lady who treated him with extreme deference and politeness until he innocently began to discourse upon the merits of his patent machine, when she said to him, with an expression of scorn and contempt: "Why, I thought you were a nobleman, but I find you are only a brick-maker." "Just as if," said the baron, "a man cannot be a nobleman if he makes himself useful to his fellow beings."

THE MIKADO'S COACH.—Probably the most costly state chariot ever yet built has just been completed for the Mikado of Japan by Messrs. Morgan & Co., Her Majesty's coach builders. The body of the vehicle is of the finest Spanish mahogany, and fashioned after an old Flemish pattern which allows an unlimited amount of ornamentation and unexceptional interior comforts. It is considerably larger than European carriages generally, but the peculiarity of its construction admits of the draft being very light. The panels are painted a rose-pale green, with white and gold trellis and scroll ornaments, the gilding being very profuse. The metal appointments are silver-gilt, the door handles and lamps being massive and richly chased. Traditional emblems of Japan, conspicuously the tortoise and dragon, surmount each corner of the roof, in the centre of which is a Japanese crown. The interior is luxuriously upholstered with cloth of gold, rich Valenciennes lace, and green silk velvet ornaments. The under-carriage is scroll-shaped and richly carved and gilt, the color of the wheels matching the body of the vehicle. Permission has been sought to have the carriage exhibited at the forthcoming horse show at the agricultural hall.—*London Times, June 1.*

High Pressure Steam.

In mechanical engineering the past year has given us no remarkable novelty, although it has not been wholly barren of results. Renewed attempts have been made to introduce steam of very high pressure as a means of economizing fuel; and much ingenuity and energy have been, and will be, we fear, wasted in the pursuit of delusive advantages which never can be realized. All arguments in favor of high pressures are based on the assumption that by using them steam can be expanded a greater number of times than is possible when low pressures are employed, and that the more expansively steam is employed, the further a given weight of the fluid may be made to go. Thus, for example, if a given weight of steam is used without expansion, and does work represented by 1, by expanding it five times we can increase the work to about 2.6, and by expanding it 100 times we could raise the duty to about 5 6. Now, it is known that the gain due to expansion has nothing to do with the pressure; but the terminal pressure in a cylinder is settled by the amount of vacuum which can be obtained. The lowest practical terminal pressure is about five pounds on the square inch, but long before this point is reached the work done by the steam will be expended in overcoming frictional resistance; it will be useless work, in fact.

Experience has proved that the lowest available terminal pressure is eight pounds to the square inch. It is obvious that if we attempt to expand steam, say 50 times, we must have an initial pressure, under the conditions, of eight times 20, or 160 pounds on the square inch. If a 30-fold expansion be attempted, then the initial pressure must be 240 pounds. It is, then, only because engineers attempt to employ great measures of expansion that high pressure steam is regarded with favor.

Up to a period of 10 or 12 years since, it was taken for granted that steam followed Marriott's law in expanding, and the coincidence—for it is nothing more—of good diagrams with the operation of this law, lent additional strength to a pure delusion. Mr. Isherwood, of the United States, was the first to show in practice that when expanding in a steam engine, steam does not obey Marriott's law, and that its consumption increases enormously as the ratio of expansion is augmented. The influence of the condenser tells heavily against great measures of expansion. Watt's so called separate condenser is only equivalent in its effects to what would have followed if he had lengthened the cylinder of a single-acting engine, and worked the piston at one end of this cylinder while he condensed at the other. In a word, the phrase "separate condenser" is a misnomer, and conveys a false impression.—*The Engineer.*

Mechanical Value of the Diamond.

Steel and new alloys are now manufactured of such density as to necessitate the discovery of new means of working them, especially where truth and accuracy are required. Steel cutters may not hold their edge a sufficient time to traverse the full extent of a face on substances so intensely hard, therefore it is important a substitute should be found of such durability as to retain its cutting edge intact, producing the same truth and accuracy of surface at the end of the work as at the commencement. Such a tool, when known to exist, will no doubt prove a valuable acquisition, and he eagerly sought for. To obtain such a tool the Societe d'Encouragement pour l'Industrie Nationale, of Paris, are offering in 1877 a prize of 3,000 francs, for the artificial preparation of compact black diamond (commonly called bort or carbonate) for obtaining thereby a powerful means of action for working hard metal substances, etc.

Among the comparatively recent mechanical arrangements are many in which the diamond is made to play an important part; in fact there is no mineral or metal that can equal it in its diversified and prospective field of application. Diamond drills, for instance, have proved valuable for prospecting mines, many being now used for the latter purpose in England, on the Continent of Europe and in America. Again, the diamond is now also being largely used in America for channelling and quarrying stone, as well as working and carving it by rotary and traversing drills or bits of various sizes and shapes, armed on their surface with black diamonds or carbonates, which are shaped with sharp angular or curved cutting edges; these bits are made to traverse and rotate at a very high rate of speed, following the interior line of a templet, producing thereby beautiful patterns of panelling of any design or depth desired in stone. The rapidity with which the work is done, and the smoothness of finish, are something marvellous. These points are also used effectively for truing hardened steel faces, such as dies, etc., also chilled iron and paper calender rolls.

HAIR CLOTH.—The only manufactory in the world where they make hair cloth by automatic machinery is in Pawtucket, R. I. Horse's tails furnish the hair, and these are purchased in interior Russia at the semi-annual faire. The tails come from Siberia. About 600,000 horses' tails are used every year. The length of the hair ranges 12 to 36 inches. The 36-inch hair, however, is so scarce that not more than three pieces of that width are made in a year.

A PRIZE FOR INVENTORS.—The Societe Industrielle du Nord de la France offers a prize of 5,000 francs ($1,000) and a gold medal worth 500 francs ($100) for the best machine for combing cotton. The following are the conditions to be fulfilled: The production must be greater than that of any other machine; a kilogramme (two and one-fourth pounds) of cotton must be turned into tow for 10 centimes, including all expenses, and the machine must be worked efficiently at least three months in the north of France.

CARE IN HANDLING MACHINERY.—The general thoughtless handling of machines, cleaning parts of machines while in motion, adjusting parts which should be at rest while being acted on, and other habits contracted by familiarity, should be avoided. A machine ought not to be trifled with. It has no remorse or pity. Once in its power, there is no escape. It should be managed with caution and constant care, for in dealing with machinery it is always better to be foolishly careful than carelessly foolish.

SCIENTIFIC PROGRESS.

Newly Discovered Mechanical Action of Violet Light.

M. Paul Bert's recent investigations as to the cause of changes of color in the chameleon have led him to a discovery of considerable importance, since it indicates a mechanical effect of light, and more especially of the violet rays, hitherto entirely unknown. He traces the changes of hue of the reptile to minute corpuscles or chromoblasts, which are located either below the dermis or at the surface of the skin, according as they are affected by certain nerves which are respectively analogous to the vaso constrictors and vaso dilatators. When the chameleon is placed half in red light and half in violet light, obtained by passing sunlight through colored glass, the portion on which the red light falls remains of the normal yellow color, while that affected by the violet light changes to a greenish black hue. This same effect can be produced by suitable nerve excitations and divisions, showing that the accession of color on the skin is absolutely caused by the rising of the colored corpuscle to the surface; while, when the latter remains inert, the natural yellow hue of the creature continues unchanged. Hence it would appear that the colored corpuscles, like certain chemical substances, are not equally affected by all the rays of the spectrum, and that in the violet blue rays alone resides the property of mechanically moving the chromoblasts and drawing them to the surface.

Similar action on contractile substances has already been noted as caused by heat and electricity; but that light should possess an exciting effect of this description is certainly remarkable.

M. Bert proposes to continue his researches to determine the influence of light on contractile matters under other circumstances, and he especially hopes to discover the reason of the favorable influence of light on the skin of children and of lymphatic persons. It seems to us he might go further and observe whether the color in the human skin, either that normally existing, as in the case of negroes, or that obtained by direct exposure to sunlight (tanning or burning), is attributable to any similar cause.—*Scientific American.*

FIBROUS PUDDLED IRON.—In a paper addressed to the Academy of Sciences, M. H. Le Chatelier adds some important information to our knowledge of this most important of all metals. The fracture of a bar of puddled and rolled iron generally presents a fibrous texture, denoting a complete want of homogeneousness in the metallic mass. This is due to the presence of extraneous matter mechanically interspersed in the iron, and which has hitherto been considered to consist of scoriæ from the puddling furnace and oxides of iron; but no direct analysis had, until now, been undertaken to settle the question, and no attempt been made to separate these impurities from the mass. Following M. Schlœsing's plan for the analysis of cast iron, our author caused a stream of chlorine to pass over a piece of fibrous iron at a dull red heat. The metal was thus entirely volatilized, leaving behind a skeleton of the exact shape of the original piece, but of such extreme tenacity and lightness that it would fall to pieces by merely blowing upon it. The color of this residue is a greenish white; it consists in a great measure of silica, with a small proportion of oxide of iron—in fact, the scoriæ mechanically enclosed in the mass, and which resisted the action of the gas, while the iron and the metalloids combined with it were completely volatilized. The proportion of this residue is about one per cent. of the whole mass. But there is this curious circumstance to be remarked, that these extraneous particles are not capriciously disseminated, but are arranged with some degree of regularity. They are all similarly oriented; they lie in long parallel files in the direction along which the bar was rolled. If it be wire, the residue will be a bunch of whitish threads; if sheet-iron, there will still be fibers, but so joined together as to form leaves bound, as it were, in a book, and admitting of being separated with the blade of a penknife. This is naturally the cause of weakness in an iron bar.—*Galignani.*

MECHANICAL EQUIVALENT OF HEAT.—The mechanical equivalent of heat may be demonstrated by a lecture-room experiment devised by Puluj. He uses two truncated cast iron cones, one fitting into the other, the outer one stationary and the inner one revolving in contact with it. The power employed for this revolution is measured by a kind of Prony brake arrangement, and the temperature by a thermometer placed in a mercury bath in the cones. By accounting for the specific heat of the iron, the mercury, etc., the mean result of 57 experiments gave the consumption of about 1,500 foot-pounds of power employed to produce one unit of heat. This is about half of the results obtained by others, as Joule, Mayer, and others, who only required 772 foot-pounds to produce the same effect; but then it should be remembered that a small machine of this kind works to great disadvantage, there is especially much loss of heat, and therefore it is not intended to obtain correct numerical results, but is sufficient to establish the fact of the convertability of motion into heat, and that the heat which can be produced from consumption of 1,500 foot-pounds is at least one unit. The unit of heat is the amount of heat required to raise the temperature of one pound of water from 32 deg. to 33 deg. Fahrenheit.

THE ROOT-CAP OF A PLANT.—A recent writer remarks: "The idea held by the earlier botanists, that the tips of all roots consisted of spongy masses of tissue, by means of which plants were enabled to soak up their food from the soil, has, with the aid of the microscope, been entirely discarded. The term spongiole, which was given to these theoretical bodies, is a landmark of departed ignorance, and furnishes a striking contrast with the known structure (the root cap), with which the tip of every growing root is covered. With the leading botanists of to-day a root is considered to be an outgrowth protected by a cap. This definition seems very short, but if anything further is added, there comes with it a number of exceptions. The name which this covering to the root-tip has received is in itself very descriptive, as it is truly a cap, consisting of a number of layers of quite dense cells surrounding the extremity. These root-caps vary in size in different species of plants; sometimes they are so small that only with the high powers of the microscope can they be seen, while on the other hand they may be readily observed with the naked eye."

THE "PANUORA" ARCTIC EXPEDITION.—The *Pandora*, which went to the Arctic regions last year, with the twofold object of discovering relics of Sir John Franklin and, if possible, of making the northwest passage, but which met an impassable pack of ice, compelling her to return home, was, in the beginning of the week, removed to Portsmouth harbor. During the last winter various alterations have been made on board. Her commander, Captain Young, was sorely disappointed at not being able to push on last year, and he hopes, on this occasion, to have better fortune. The *Pandora* has two years' provisions on board, but the period of her absence is, of course, uncertain. She will take letters for the Arctic ships, and was expected to leave on Thursday, touching, it is thought, at Disco to coal and receive on board some Esquimaux dogs, and then push upward to the mouth of Smith's sound, and endeavor, if practicable, to communicate with Captain Nares' expedition. Smith's sound, it is hoped, will be reached about the end of July, after which Captain Young will, if everything goes well, endeavor to make his way through a northwest passage.—*Iron.*

SUCCESS OF ZINC AS AN ANTI-INCRUSTATOR.—The German industrial papers contain reports in regard to the success of zinc scraps as a remedy against the incrustation of steam boilers. Bruckman & Sons, of Heilbroan, report the following: In a steam boiler of 25 square meters (250 square feet) heating surface, and a new mud drum, 30 kilograms (64 pounds) of zinc scrape, large and small pieces, were placed; the feed water was the ordinary spring water of the city water works; after six weeks a gray slimy mass was found adhering to the boiler, which, however, was completely removed with the greatest ease. The boiler was then washed out by means of the spay from a hose, and became perfectly clean, so that the iron of the mud drum looked as black as when new, while in the boiler only here and there old remnants of scale were visible, but new deposits had not been formed. Remnants of the zinc were seen in small corroded fragments, and at the same spot where they had been laid down at first.

SCIENCE IN BRAZIL.—A Frenchman of science, M. Steenackers, the superintendent of telegraphs during the time of the "defence nationale," is conducting scientific instruction in Brazil. The government has given him a well fitted laboratory, and he finds his pupils intelligent and hardworking. His lectures are given in French, in the evening; they are noted down by the students, translated into Portuguese, and published in a special paper. Popular information on primary matters is very small. Certain local industries are curious; among them is the distillation of gas from the seeds of the castor oil plant. Cotton spinning and weaving works, with or without dye works, are not scarce. At Rio is a stearine candle factory, working successfully with the best modern appliances, saponifying by water under pressure, and distilling with superheated steam.

Mining Share Market.

Either the public has become so much interested in the coming Centennial celebration that they take no interest in the stock market, or has become apathetic for other reasons, but at all events there has been no animation whatever for a week past. The whole line of stocks is weak, from highest to lowest along the whole range. As a great amount of money will soon be required for use in handling the California wheat crop, there seems to be no likelihood of there being any great improvement in stocks this summer, unless there shall be made a grand strike in some of the mines. Many millions of dollars will be required for the moving of the wheat crop, and it will be a long time before this money is again free and placed where it can be used in stocks. Perhaps after the holidays there may be some improvement. The stock boards will adjourn for this week until Thursday, July 6th, at 12 M.

The only topic in stock circles of special interest is the anticipated election fight for the control of Savage. Contradictory statements of James Keene, J. G. Fair and others concerning the management of the mine have been published. The election takes place on the 20th of July, and an effort is being made to oust Flood & O'Brien from the management. The "ontside" party allege, as reasons for their proceedings, that the mine has been systematically mismanaged, heavy assessments have been unnecessarily levied, and the majority of the stockholders are dissatisfied. So stands the case at present, and it would be premature as yet to advance an opinion regarding the result. The affair, however, is the prime topic on the street and in mining circles, and excites a very general interest and excitement.

On the Comstock the *Enterprise* expects soon to see a season of greater activity than ever before. The two huge new mills of the Bonanza mines are being rapidly pushed to completion, and the new and powerful machinery of the Savage mine and the Hale & Norcross will shortly start up and drain those water-logged mines, when the miners will again be able to descend to the lower levels.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

New Claim.—Alpine *Chronicle*, June 17: We learn that a new claim—the Jennie Nettle—has been started up at Monitor by Matthew Nettle. Our Monitor friends are getting somewhat excited over the mining prospects of their district, and they have good reason for it. Outside of the Tarshish, or Schenectady claim, there has been no legitimate mining at our sister town until within the past six or eight months, when the Advance shaft was started for deep mining, agreeably with the report of J. Ross Browne to the Government in the early days of our county. He said that we would have to go deep for paying ore, but that we would be well paid by so doing, as we would open up inexhaustible mines of the precious metals; and the shafts now being sunk in the county are tending to verify his report.

The Exchequer.—The mine is being retimbered in many places, preparatory to more active operations when the new furnace is erected at the mill. At the mill the old furnace and building are being removed to make room for an O'Harra champion furnace of a capacity of 30 tons a day; and to keep in tune with the furnace the mill will have 10 stamps added to it while the furnace is going up. The saw mill has been getting out timbers for the new furnace building. Manager Chalmers has placed his residence at the mill in fine order, and it is now as comfortable as an old English mansion, and everything about the place betokens an intention on the part of the manager to make it a permanent home—a good sign that the mine is not going to collapse.

Lady Franklin.—Work on the mine will probably be commenced soon and pushed forward with energy. This mine is in Scandinavian canon, and about two miles from our town. It joins the Exchequer mine and is a most valuable property. The company have a U. S. patent to it. If this mine is worked as it should be, it will not be long before it will pay a dividend.

AMADOR.

Daytown Mining Items.—Cor. Amador *Ledger*, June 24: Within the last few days it has been discovered that there is a continuous quartz ledge running through the west side of town, which is thought to be rich in gold and sulphurets. The ledge has been located by Messrs. Belding, Henderson, Murdie and Thomas. The work of sinking an additional 50 feet in the shaft of the Bonanza mine has just been completed. They are now opening up a new level. Everything looks flattering. The Crown Point company are now crushing some of their rock at the Centennial mill, with satisfactory results. Drytown is looking up. Persons who have not visited the place lately would be struck with the altered condition of affairs for the better.

BUTTE.

Claim Sold.—Oroville *Mercury* June 23: Last week we stated that Dr. A. K. Stearns had gone to San Francisco to consult with Hon. G. O. Perkins and Mr. Kelley in regard to building a new mill for their mining claim. Instead of building they sold the claim to Messrs. Craig & Co. for the sum of $20,000, cash down. A new mill will soon be erected.

CALAVERAS.

Quaker City.—Calaveras *Chronicle*, June 24: Everything is progressing finely at the Quaker City mine, near the Junction. Levels are being run at the depth of 200 feet, with fair prospects of striking the ore body at a short distance. Prospecting is the order of the day, and the managers of the mine show no disposition of falling into the very common error of erecting expensive machinery until developments warrant the outlay.

Grasshopper.—The machinery at the Grasshopper mine at Mosquito is now running nicely, keeping the works free from water. Labor is progressing, prospects are brilliant and everything lovely.

Rich Rock.—A lot of quartz from the mines belonging to Gase & Co., Glencoe district, lately crushed in Garland's mill at Mosquito, paid an average of $62 per ton. We learn that the company have sunk a shaft about 90 feet deep on the ledge, and that the prospects for the development of a first-rate mine are very flattering.

San Bruno.—A new pump for the San Bruno mine at Mosquito passed through here Wednesday last. We believe it has not been put into the shaft yet, the old one having sufficient capacity to keep the mine free of water. We understand that a good sized ledge, composed of rich rock, has been struck in the east level.

Josephine.—We continue to hear very favorable reports concerning the Josephine mine at West Point. Splendid ore is being obtained and operations are being vigorously pressed.

South Calaveras.—Vallecito Cor. *Chronicle*: The Morseville mining company have resumed work on the old "Tyler" mine, located near Murphys, and are taking out some of the richest ore ever shown in the county. The company have erected an arastra and mill, and have been steadily engaged crushing rock during the past six months, the ore yielding the unusually large average of $80 per ton. The Frazier mining company's claim, about a mile west of Murphys, is supposed to be an extension of the Tyler. The company have been taking out rock for several months past, and are intending to erect a mill as soon as practicable. The Elizabeth Tilton and Ward Beecher Consolidated mining company's claim is located two miles north of Vallecito, on Kelly's gulch. Rock of extraordinary richness is being taken from the mine. The company lately commenced crushing with their improved water mill, and results so far are highly satisfactory.

EL DORADO.

Union Mine.—El Dorado *Republican*, June 22: Under the superintendence of Dan C. Wickham this mine, more familiarly known as the Church Union, situated about three miles north-west of El Dorado, is developing into a splendid property. Formerly the machinery was run by steam, and was shut down several years ago because it failed to pay under extravagant management. Last fall the present owners had all the works remodeled and rebuilt to run by water power, and everything works to a charm. These changes made an immense saving in running expenses, estimated to be fully $40 per day. They are now taking out very fine ore, the shaft being down about 300 feet, and pays better and better as they advance. It is estimated that the mill, a ten stamper, is now turning out $300 per day on an average. Twenty-one men are employed about the mine.

KERN.

Rich Developments.—*Southern Californian*, June 22: From Mr. Joseph Ginaca and Mr. J. S. Collins, who arrived from the mountains on Monday, we get tidings of the Harley mine, the Consolidated Buunell company, above Kernville. The tunnel has now advanced 150 feet and the developments continue very flattering. The tunnel is completed and a fine head of water has been flowing through it for six weeks past to the lower mill site. The mill building, offices and shops are finished, and the only delay in the placing of the machinery is the want of brick, now being made near the mine. The buildings of Ruby City are being rapidly constructed, and the promise of a town rivaling the prosperous town of Kernville is exciting a good deal of attention. It is expected to have the ten stamps running within a month, with plenty of high grade ore to keep them working an indefinite time. Another company is about to commence work on a continuation of the Harley ledge. Several other ledges have been discovered which remarkably rich croppings, and located. There seems no doubt now that the Harley mine is the main vein and the others are tributary to it. The face of the tunnel is doubtless in the mother lode. It is said to be impossible to find a specimen of any size in the Harley tunnel which will not assay $100 per ton. The work is being prosecuted with great vigor night and day, with from 30 to 40 men. Fifty men are employed in different branches of the enterprise. The Harley company is composed of Chas. Harley, Joseph Ginaca, J. S. Collins, A. O. Collins, John Dunn and L. W. Burr. The mining prospects of Kern county grow in prominence, and with the advancement of the enterprises now inaugurated we should rank the first in the State. The recent locations, with the reports of experienced prospectors, indicate the Ruby mountain to be teeming with mineral wealth.

PLACER.

Dutch Flat Items.—Placer *Argus*, May 24: Mining in and around town is in a flourishing condition, encouraging reports being had from all the claims. On Saturday last a blast of 250 kegs of powder was exploded in the Polar Star claim. The drifts were from 40 to 120 feet in depth, and there were five chambers or T's. The results of the explosion were all that could be expected. Water was turned on Monday morning and washing resumed. The tunnel in the Yankee claim is being pressed forward rapidly, work being continued day and night, and is advancing at the rate of about seven feet daily. The water supply in all the ditches is yet full, and may be expected to continue so for probably a month yet. The intense warm weather of last week, by melting the snow rapidly, will have the effect to diminish the flow earlier than would otherwise have been the case.

Mining Items.—Dutch Flat *Forum*, June 22: The Elmore Hill, Pacific, Dunning, Franklin and Boston claims continue washing. The Lekamp and Summersett claims have just been cleaned up and are now refitting. The Badger and Yankee claims, since the plug in the Badger shaft was cleared out, have been washing ten hours a day. At Gold Run the Indiana Hill and Cedar claims have cleaned up since our last report, and with very satisfactory results. Both of these claims have refitted and are washing again. The Gold Run, North Star and Sachs claims continue washing.

Water Supply.—The ditches of the Cedar creek, South Yuba canal and Minor's ditch companies continue to convey their full capacity of water, and it is supposed that they will do so for at least a month to come.

Green Valley Mines.—The Green Valley mining company is progressing rapidly with the shaft, which is now down 80 feet, and still in quicksand. The water which drove them out at 15 feet is kept under control by a cast iron pump worked by an overshot wheel. They will reach bedrock in about 10 or 15 feet more. The Superintendent, V. Souder, was under the impression that there was another channel further in the hill, so accordingly set men to work running a tunnel in bedrock. He was correct. At 72 feet they ran through the bedrock into a channel of washed gravel which prospects well in fine gold; the depth of this channel is not known yet, but is supposed to have been the main river bed at one time. The Hidden Hill mining company made another partial clean-up last week, the result being over 100 ounces of coarse gold. They have still considerable bedrock to clean, which will pay well. Their dividend this year will be large. The Beardsley claim and Norvey & Co. are still drifting and doing well.

Iowa Hill,—Placer *Herald*, June 24: We learn from ex-supervisor Van Vactor, of Iowa Hill, that quite a number of the hydraulic mines in that district are still running at full blast. The season, to be sure, is getting well advanced, the harvest is nearly over, and yet it is gratifying to know that, with scarcely an exception, those mines in the district which are properly opened and well fitted up, have yielded during the season very encouraging results.

PLUMAS.

Shoo Fly Claims.—Plumas *National*, June 24: Mr. F. Atherton, of Shoo Fly, was in town on Monday, and brought along a nice little sack full of splendid looking dust, the result of a short run in his claims. His ground is first-class and when he gets his improvements made he will develop something very rich.

North Fork Items.—The North Fork company at Dutch Hill, under the admirable management of Mr. S. Scott, are pushing the work in all three claims. Your old townsman, Jno. E. Smith, is foreman of the hydraulic works at Barker hill, and is cutting dirt very rapidly with a fine head of water from the "big pipe." The pump engine at Cumming's hill works well, and large returns are expected from that claim. At Carriboo, all the water that will run through two large giants under a pressure of 320 feet is being utilized, night and day. This claim is fitted up in good shape, and all the gold in the claim will certainly be saved. The boulders in the face of the claim are heavy and necessarily cause slow work. A large derrick will be put into use as soon as the claim is thoroughly opened. Orton, Keep & Co. have struck good looking gravel on the same channel that Keefer is working, near the Deadwood bridge.

Items.—Work on the Pierson blue gravel claims, near Nelson, has been resumed. A shaft will be sunk, and a water wheel will do the hoisting. We will have some good reports from this claim this season. The Smith Bros.' claim at Butterfly has been paying big in coarse gold, and we hear of nuggets weighing $50 having been found lately. The Maxwell company are pressing work on their canal down the river. Our old townsman, John Dow, was in town the other day. John says the East Branch is lovely, and the miners all prosperous and happy. Harry Gregg has sold the Grass ledge, near Cherokee, to the Green Mountain company. He now has a contract for hauling quartz to Dixie mill. The Argentine mill will be put upon the Buchanan mine, near Indian valley. The rock now being crushed in the Crescent mill is paying $20 per ton.

SONOMA.

Important Developments.—Sonoma *Democrat*, June 24: Tuesday, in the shaft of the Taylor Mountain coal mine, two and a half miles from Santa Rosa, important developments were made. Coal in considerable quantity was struck, which far exceeds in quality anything heretofore taken out in this section. A cube of coal about a foot in hight and from eight to 10 inches in width was exhibited this morning, and created quite an excitement in the city. It is a lignite of very superior quality, harder and more compact in structure than that mined at Mount Diablo. The fracture is different from most of the Pacific coast coal which we have seen. Its solidity indicates a less percentage of water, and it will not, in consequence, slake as readily as the Mount Diablo and Coos bay coal. It leaves a light, white ash, and but little of it. It does not leave more than one-third as much ash as the Bellingham bay coal, and is free from the earthy matter which characterizes that coal. In short, it is equal to the very best coal yet found on the Pacific coast, and if it proves on further development to exist in quantity, it is without exception the most important discovery yet made for the future welfare of this city.

Nevada.

WASHOE DISTRICT.

Sierra Nevada.—Gold Hill *News*, June 22: Sinking the new shaft is going steadily forward, the bottom in soft porphyry mixed with a white, calcareous marl, full of sulphurets of iron. There is no flow of water at the bottom, it being caught by the tanks above. On the 1000-ft level the main south drift is steadily advancing, following the east wall of the ledge, the face in clay and porphyry, mixed with light streaks of quartz. Its length is 540 feet. The main north drift on that level is in 450 feet, the face in porphyry and clay. On the 1200-ft level the main south drift has been advanced 250 feet, and the main north drift 150 feet, both in very encouraging ledge material. The main east drift from the 1500-ft station is in a distance of 600 feet, the face in hard porphyry.

Con. Virginia.—Daily yield, 500 tons of ore, keeping the mills running up to their full crushing capacities. The mine is looking well throughout, and promises a rich yield of good ore for a long time yet to come. The west drift from the C. & C. shaft has been advanced for the past two weeks at the unprecedented speed of ten feet daily, and if no unforeseen circumstance prevents, will connect with the drift going east by next Saturday. The north drift on the 1700-ft level is steadily advancing, the great heat allowing of but slow progress. Sinking the C. & C. shaft is making good progress. The frame of the new amalgamating mill is up and the other portions of the work well advanced.

Ophir.—Daily yield, 300 tons of ore. The ore is of good quality and is being reduced at the mill as fast as it is extracted. The ore stopes on the 1600-ft level are showing splendidly, both north and south. The north drift on that level completed the connection day before yesterday with the north winze from the 1465-ft level, thus affording a much better circulation of air, and greatly aiding the operations on the entire 1600-ft level. The face of the east cross-cut on the 1100-ft level is still in quartz and low grade ore. About 200 tons of ore is being hoisted daily for the California mine. The hydraulic works for elevating the ore to the dump at the railroad is working splendidly.

North Con. Virginia.—The excavations for the heavy foundations of the new pumping machinery are completed, and a large force of workmen are busy putting in the stone foundations. A portion of the pumping machinery is already on the ground ready for erection. Cutting out for the bob pits and water tanks in the shaft is going ahead rapidly.

Bullion.—The north drift on the 2000-ft level has been greatly delayed during the past week by the stoppage of the Imperial pumps. However, the work will be resumed in the face of the main drift in a day or two more, when it is confidently expected that the main ledge will be cut. On the 1700-ft level the upraise is making good progress with a fair prospect of soon connecting with the winze from the 1400-ft level, as the workmen can now distinctly hear the sound of each other's work.

Gould & Ouray.—Repairing the main shaft is making better progress than for some time past. The foundations for the new pumping machinery are being forwarded at a very rapid rate; in fact the entire preparation for the erection of the machinery is now in an advanced state, and its completion is but a matter of a very short time. The boilers which are to furnish the steam for driving the exhaust air mill at the mouth of the old lower tunnel are in place, and everything will be ready to start up the entire machinery in a very few days.

Rock Island.—A day or two ago a heavy flow of water was encountered in the face of the main west drift on the 850-ft level, partially flooding that station and causing a temporary suspension of the work on that level. At the time of striking the flow of water the face of the drift was in a much livelier and better formation, carrying streaks of finer quartz and clay than has been before encountered in that direction.

California.—Daily yield, 350 tons of ore. The ore is of the usual rich quality, and the ore breaste continue to open up splendidly. Beyond this there is but little to be said of the mine. The yield of bullion for the month of June will reach, if it does not exceed, that of May. The erection of the new 80-stamp mill is going rapidly forward and it will soon be ready for the reduction of ore, and when completed will add at least 350 tons more per day to the reducing capacities of the Consolidated Virginia and California mines.

Savage.—The hoisting engines are in place almost ready for starting up. The coping stone for the sole platee of the huge pumping engine are in place and are being dressed ready for the reception of the engine itself. The huge driving wheel is being placed in position and it will be now but a very short time before the whole will be ready for work.

Mexican.—The connecting of the north drift on the 1600-ft level of the Ophir with the bottom of the north winze from the 1465-ft level has greatly benefited the circulation of air in the Mexican drifts, and will now permit of the immediate commencement of crosscuttiug the ore vein at different points on the 1465-ft level.

West Belcher.—Work in all the prospecting drifts steadily advancing. The ore dump will be completed and ready for the reception of ore in about two weeks' time. As soon as that is finished, shipping and milling ore will be commenced.

Imperial.—Daily yield, 30 tons of ore, of a good quality. The north winze on the 2000-ft level is down 86 feet, the bottom still in rich ore. Sinking the south winze on the same level, to complete the air connection with the Yellow Jacket, is making the usual fair rate of speed.

Belcher.—Daily yield, 400 tons of ore. The ore stopes going south on the 1500 and 1200-ft levels are still showing finely. The erection of the new pumping machinery is being rapidly pressed toward completion. A large number of mechanics are employed on every portion of the work, and the site of the air shaft presents a lively, determined and business-like look. The shaft will be completed ready to commence the hoisting of water from the 1700-ft level by the time the pumping machinery is completed.

Hale & Norcross.—The yards surrounding the works present a crowded, busy aspect. On every hand are piles of huge castings, pump columns and other portions of the new machinery now in course of erection. The foundation for the new pumping engine is ready for the coping stone, and the erection of the entire machinery is being advanced at a very rapid rate. The clearing of the shaft of the old pumps and columns and the enlargement of the tank stations and bob-pits is going steadily ahead.

Yellow Jacket.—Sinking the north winze below the 1040-ft level is making good progress. Driving the south cross-cut on the same level is going steadily forward, the face still in porphyry mixed with quartz.

Crown Point.—The main south drift on the 1700-ft level is being pushed ahead, the face still in quartz and low grade ore. The production of ore has been cut down to just enough to keep one mill, the Rhode Island, employed.

Superior.—The new machinery being completed, with a good house over the shaft and works, sinking is resumed in the shaft, which is 110 feet deep. Considerable water has to be raised, but it is easily handled.

Lady Washington.—The additional pump, for the working below the 200-ft level, has arrived, and will be put in immediately.

North Careon.—The introduction of water by a mile or so of pipes laid from the flume of the Virginia and Gold Hill water company being completed, the new works have started in full operation to-day and work is resumed in the mine.

Twin Peaks.—The splendid vein of regular Comstock ore found at the 75-ft level is showing better and more extensive than at last report. It gives good assays and bids fair to develop into a bonanza.

Justice.—Daily yield, 60 tons of ore. The ore is of a good quality, and the stopes at all points are showing splendidly. The mills are kept running up to their full crushing capacity. The face of the south drift on the 800-foot level is showing finely, also, the north drift on the same level. The north drift on the 1000-ft level has encountered some very fine quartz and ore.

Overman.—Daily yield, 30 tons of ore. The ore stopes on the 900 are showing somewhat better than for some time past. The main west drift on the 1200-ft level has penetrated to the west side of the ledge, and two drifts have now been started, one north and the other south, to determine the value of the vein.

Chollar Potosi.—Daily yield, 120 tons of ore. Sinking the main incline is making good progress. Sinking the new combination shaft is also making excellent progress. The erection of the huge pumping engine for this shaft is going steadily forward. The hoisting engines are now nearly ready to start up.

Julia.—The flow of water from the 1800-ft level still continues quite strong and the water very hot. Both the main south and west drifts on that level are steadily advancing, the face of both showing fine quartz and low grade ore.

Silver Hill.—The recent flow of water is drained from the main incline, and the sinking is again making good progress.

Caledonia.—The flow of water is still strong, but the pumps are gradually lowering it; proving that the supply is slowly decreasing.

Ward.—Sinking the main shaft is making splendid progress. A set of timbers, making five feet, is added each day to the depth. The erection of the foundation for the new hoisting works is going rapidly ahead.

Prospect.—Sinking the shaft is going ahead at the rate of three feet per day.

Belcher.—Small streaks of favorable looking quartz are met with in the face of the west drift.

Nevada.—Face of the main west drift continues in low grade ore, with streaks of porphyry and clay.

South Consolidated Virginia.—West drift showing considerable good ore and very encouraging prospects.

Dayton.—Sinking the main shaft has been resumed. The new lift pump is working splendidly.

Vivian.—Yielding the usual amount of good milling ore from the old stopes and breasts, with a fair contribution from the 1200-ft level.

Lady Bryan.—The excavations for the new machinery are steadily progressing.

Consolidated Justice.—Good ore is being taken out from the upraise for milling, and the face of the main north drift is showing finely.

Alta.—The new pumping machinery will, it is confidently expected, be ready for full service in a very few days.

Brooks.—Preparations for the erection of the new and more powerful pumping machinery have been commenced.

Oregon.

Virtue Mine.—*Bedrock Democrat*, June 14: On last Wednesday another clean-up was made at the Virtue mine mill of $10,000 and the bullion shipped to San Francisco. Superintendent Hyde is working this mine very economically and making good returns for the owners. The new hoisting works building is about completed and reflects credit on the workmen, Messrs. Crabill & Sprague; the furnace is up, and the boilers, of the latest and most improved pattern, are set and ready for operation, and the balance of the machinery will soon be put in place, after which we expect to hear of large and quick yields from this mine. The mine is now of such a nature that there can be none of the stock bought in the market at San Francisco. This speaks well for the Virtue mine.

Foundry.—It is with pleasure that we announce the fact that Superintendent M. Hyde, of the Virtue mine, intends to erect an iron foundry in our city, where all castings necessary for quartz mills and other machinery can be procured. He has all the machinery and material necessary for the business, and expects to have the foundry in operation early in July. He has an experienced foundryman engaged, and intends to do good work and furnish first-class castings.

Idaho.

Local Mining Notes.—Idaho *Avalanche*, June 24: We have nothing new to report this week in connection with the situation of mining affairs. The general impression is that one or two of the mines hitherto remaining idle will start up in July. The great point with the companies is to wipe out as much of the indebtedness as possible and reduce the bulk of the claims against the mines, so that as few barriers as possible will exist in the way of resuming work. We earnestly trust that all parties interested will see the necessity of making every sacrifice possible consistent with the public good. It may be many long months before these suits are decided, and in the meantime much valuable time is being frittered, summer is passing away and the season for getting supplies to the mines for the fall and winter campaign will soon be at an end. The salvation of the camp depends upon the resumption of work this summer, and to this end we appeal to every claimant to make sacrifices now and take his chances for making up losses out of future operations.

(Continued from Page 2.)

one think I am forgetting the farms, those gems of

Lillie Farms Well Tilled

That not only dot the valley hut cover it with closest links of verdure. We can have no quarrel with the religion of these farmers es we look upon the work of their hands and see that industry snd economy are blessed here as they deserve to be everywhere. Crops are not far advanced, some just out of the grounds and the tallest grain only a few inches high; but these are the last days of May, and they say the season is not forward as usual. Pasture grass ia rank and rich; good hutter on our table, and all food good and cheep both at Ogden and Salt Lake.

We visited the tabernacle, and were pleased to find the inside so bright and cheerfnl. Wreaths and immense hanging haskets and vases are greefully hung in the wide dome, and in the central sisle is a large marhle basin ornamented with crouching statues, and here, when Sabbath days are warm, ths fonutain pleys for the cooling of the people. Twelve thousend can be seated here, and for exit 20 doors, nine feet wide, open outward. The tabernacle is only used for summer worship, as there is no heating apparatns.

And how shell I describe the organ? It is immense and heautifnl, larger than many a modest cottege I have known, and it tekes four men to hlow it. Our guide said it is the largest organ in the world and thoroughly Mormon in design and execution, wholly the product of home talent and home material. This guide or janitor of the holy places was quite an elderly man, nimble and talka'ive. As we asked after the health of Brigham, he straightened himself and answered with enthusiasm, "I am happy to say, sir, that

Our Presidenl

Is again in excellent hesith and is making a trip in southern Utah. He is 75 years old today, and looks ahout 60. Why, sir, he walks off as straight and strong as I do," and upon this, away he went leading the way to the tabernacle, and put us all to shame, for his dapper legs sped along over the walk as though the springs had been newly oiled and meant to run forever. We afterward met him on the street, outpecing everybody, and could not help laughing at the pains he took to impress us with the spirit and extreme youthfulness of

Veteran Mormons.

Of course we were too polite to ask him how many wives he has.

We went into the art gallery. Well stocked with the usual pictures and excellent stereoscopes, at San Francisco prices.

This day (June 1st,) was not only Brigham's birthday, but monthly fast day with the Mormons, and services were held in all the werd churches. We went into the one near Brigham's house and saw two of his wives, rather heavy, ordinary lookiug women, with ruffled gowns and stylish hats. The service was condncted hy the President's brotber, Joseph Young, and the prayer wes very fervent, after the ancient Methodist style in manner and expression.

Nothing could exceed the zeal with whicb he demanded blessings for the saints, and especially for Bro. Brigbam. "O, Lord, hless him in his hones and in his flesh; in his head and in his body, and in his stomach; bless him, O, Lord, in all the functions of his tahernacle." This was twice repeated like a lesson, and is correctly reported. If prayer can hold him together, Bro. B. will last a long time yet.

The exhortation was lively and reproachfnl, for the saints had not come up gladly to the house of the Lord, and the few who were present took meekly the censure that should have fallen upon the absent. There were present only 13 women, five men, including the speaker, and a few children.

A man with a loud clear voice played the organ and "carried the tune" at such a rate we could hear no voice hut his, although some of the women moved their lips as if faintly helping.

As our time was limited, we could not qnite finish the usuel course of sight-seeing, but returned well satisfied to Ogden on a special train that took up a director and the president of the road to inspect the break in Weber canon.

The Engineer.

A Railroad to go Across the Eastern Continent.

The great feat accomplished hy the United States in connecting the Atlantic and Pacific oceans by a railroad across the United States is stimulating enterprise in Europe, and it is now proposed—indeed, the plan is matured—to connect the Atlantic and Pacific oceans by a railroad through Central Asia. At a conference of the geographers, recently held, Col. Bagdanowitz explained some of the details of the road, which, it is expected, will overcome one of the greatest obstacles to the extension of civilization—namely, the separation of a large part of Asia from Europe by vast deserts, in which no means of transit but a railroad could he of any use. A railroad alone can develop the resources through which it would pass. The mineral wealth of Siberia and the Ural mountains is well known. The exploration and mining of their region would be encouraged and their resources developed. It is proposed that the road shall start from Nijnii Novgorod, in Russia, where now is the extreme eastern station in the network of European railroads. It will run along the Volga, the Kama to Ekaterinhurg, on the Asiatic side of the Ural mountains; then enter Asia, proceed in the direction of Truemen and Gmsk, at the Irtish, across the river, proceed by the way of Kainsk to Tomsk on the Tem, a branch of the Obi, and across the river. Tomsk is the principal center of commerce of Western Siheria; thence the road will run directly to Irkutsk, at Lake Baikal; thence the road is to pass to the frontier of Chins, and thence it is no longer an exclusively Russian hut an international undertaking. The first section, from Nijnii Novgorod to Tomsk, runs on perfectly level ground (the so-called steppes), eimilar to our prairies. In the second section, from Tomsk to Lake Baikal, the country is rolling and interspersed with rivers end streams; but the greatest hight is only 3,500 feet, and the largest rivers are but very moderate width and depth. The only serious difficnlties, as we have said, lie at the Chinese frontier, and they are inferior to those overcome in the Rocky mountains and the Sierra Nevada by the American engineers. Russia has raised in 15 years more than $1,000,000,000 with which to construct 15,000 miles of railroad, and can easily find $300,000,000 or $400,000,000 to construct a line of such value to all the civilized world.—*Iron and Metal Review.*

The Flooding of the Sahara.—Mr. M'Kenzie, with a party of ten, will leave London in the heginning of next month for Western Africa, for the purpose of meking the necessary surveys preliminary to turning the waters of the Atlantic into the great sink or basin which extends from the valley of the Bella to Timbnctoo. He is very confident that a canal eight or nine miles long will accomplish the great operation which he contemplates, and hring the mysterious capital of equatorial Africa within six or seven days' sail of the Thames. If he snceeds, there can be no doubt as to the immense development of trade that will ensue; aod to some extent the condition of the natives will doubtless be ameliorated, although the introduction of Enropean civilization has not always proved an unalloyed good to the negro races. And even if the main project fail, there can be little difficulty in estahlishing a good land route, with a base at some of the points accessible to shipping; for the climate at this point, on the parallel of the Canary islands, unlike that of the present commercial depots, suits European constitutions well enough.

A New Drawbridge.—A recently patented drawbridge, designed to afford perfect facilities for crossing navigable streams without impeding navigation, is the invention of Lieut.-Com. H. H. Gorringe, U.S.N., of Washington. The bridge is composed of a number of floats, each pivoted or hinged at one end, the other end being moored to anchor piles hy means of a chain passing over a windlass on the swinging end of the draw or leaf. By revolving the windlass the draw or leaf may he swung clear, so es to afford vessels a single passage ns wide as the length of the draw; a reverse motion of the windlass closing the draw and opening the roadway. Since this operation may be performed with either or all of the floats, vessels may pass trough the bridge at any point selected, or the whole width of the river may he thrown open to navigation. The inventor, among other things, claims "cheapness aud facility of construction, greater security than ordinary bridges, freedom from obstruction to navigation, and from risk of damage hy freshets, moving ice end other floating hodies "

The Pneumatic Railway in Paris.—The *poste atmospherique*, for the dispatch of messeges between Paris and Versailles, has just been completed, and is nearly 13½ miles in length. The tubes, which are made of bress, are 13 feet long, three aud a half inches in diameter and two-fifths inch thick, are laid at a depth of eight feet from the snrface, on a flooring of wood, and are pitched both inside and out. The route outside the walls of Paris is elong the highway No. 10. Inside the city they are suspended in the sewers. At the Bridge de l'Alma the tube hifurcates, one portion passing to the Palace de l'Elysee, the other to the Central telegraph office. At Versailles the terminus is in the new hall now heing huilt on the left wing of the palace.

The East River Bridge.—The question of continuing work on the East river bridge will shortly he argued hefore the United States Circuit Conrt in New York city. A lessee of one of the United States bonded warehonses, sitnated on the river side above the piers of the bridge has presented a petition for an injunction, restraining the mayors of New York and Brooklyn, tbe hridge company and others interested, from building the bridge "over the East river at the hight of 135 feet above mean high water, or at any other hight that shall obstruct, impair or injuriously modify the navigation of said river." The petitioner declares that the structure would irreparahly injure his husiness.

Multiple Drilling Machine.—The *Engineer* shows a multiple drilling machine, especially adapted for drilling plates in position on straight or hog-backed girders. The drills may he adjusted at any distance apart, and to suit varying pitches of holes, and while they may be brought together within three and three-fourths inches, the driving wheels, by passing each other upon different levels, may be nearly six inches in diameter. The feed is automatic or independent at will.

Results of Captain Eads' Work.

Miller, Dolhonde & Co., of New Orleans, say: We have some intereating and valuable news to impart to our friends and correspondents, and which will benefit also the general interests of this city and those of the Mississippi valley. Captain Eads' jetties are improving daily, and this week a large steamship, drawing 14½ feet, came through them (the Sonth pass) without meeting any impediments, and before winter, from present indications, that route will be the favorite and shortest one to and from the ocean for the port of New Orleans, and will give all the weter necessary for the largest vessels. The public news from Washington to-day is thet parties from New York represent the feeling there regarding the jetties as entirely confident. Commodore Garriaon, who has heen watching their progress with a view of placing a line of steamships between New Orleans and Brazil, hes made no halt in his preperations. Dom Pedro has heen approached, and there are assurances thet his government will pay half of what may be necessary to carry the mails, and movements are afoot to secure a contingent contract from our government for carrying the mail. At present there is ample tonnage here for cotton, but on account of insufficient water yet at the mouth of the river, vessels cannot take all the freight they can carry to load deep with, such as grain and provisions, hut in a few months our Western friends will have no cause to complain, and will be realizing the full benefits of this port and market, which will prove in the near future the best in this country for the distribution of cotton, provisions, breadstuffs and Western produce genera ly. This city will have different railroads running to Texas within this year —and, with the above all accomplished, New Orleaus will offer the hest field for capitalists and manufacturers; property and business will increase materially. Thus is the public benefited by the labors of the skillful engineer.

Another Ship Canal Projeot.—A import ant water cut-off is suggested by the leading commercial journals of Europe at the present time. It is a ship canal from Bayonne, in the Bay of Biscay, through Toulonse to Ayde, which is two miles from the Mediterranean. This improvement, if constructed, would make almost a bee line from Plymouth, England, to Malta, and save the long run down the coasts of Portngal and Spain. This at present amounts to some hundreds of miles. When all the advantages of the projected improvement ere carefully considered, its paternity can readily he fixed. It is England that would profit most from such a shortening of the road to India. With a ship canal across the southern end of France, vessels could leave Liverpool or any other English port, pass readily and quickly into the Mediterranean, and from that sea by the Suez canal into the Arahian sea, and thus reach her possessions in India.—*Times.*

Monolithic Aqueduct.—The aqueduct from La Vanne to Paris, 135 miles long, is nearly entirely of *beton Coignet*. The Fontainebleau section of 37 miles, over dry quicksand, is composed of a series of arches, some of them 50 feet high. Eight or 10 bridges of spans from 75 to 90 feet, are also of *beton*. For foundations and gravel walls, the composition is send two and one-half, gravel two and one-helf, hydraulic lime one, Portlend cement one-fourth. For pillars, abutments, etc., sand four, hydraulic lime one. The other portions, sand four, hydraulic lime one, Portland cement one-fourth to one-half.

Engineers in Her Majesty's Service.—The report of the parlimentary committee into the position of the engineers in her Majesty's service has heen issued. Its chief recommendations are thet engineers shall he executive officers, chief inspectors and inspectors to rank with captains, chief engineers with commanders, and engineers with lieutenants. A considerahle increase of pay, compulsory retirement, and appointment of chief engineers to ships under a commander. The recommendations will greatly add to the nnmber of that class, and therehy facilitate promotion.

The New Silver Bill.—The new silver hill introduced hy Senator Christiancy as a suhstitute for the Fiuance Committee's silver hill, now pending in the S nete, contains the following es its main features: Silver coins of 25 and 50 cents to be made legal tenders for $10, and smaller silver coins for the amonnt of $5. A new silver dollar of double the value of the half dollar is to be coined and made a legal tender for amounts not exceeding $10. Silver bnllion, in bars, stamped by the mints with their tare, weight and finenesa, and also existing trade dollars, are to be made legal tender for the payment of all debts, according to their market valne as compared with the present gold standard. The market value of silver is to be determined and publicly announced from two to three days before the first of each month by a board, consisting of the Secretary of the Treasnry, the Director of the Mints and the United Statea Treasnrer. The bill also authorizea the mints to issue quartera, payahle in the minta' silver bara, and provides that silver coin shall be exohangeable for United States notes at their nominal valne, which shall thereupon be permanently retired and made part of the sinking fund. It is also provided thnt the Treasury maintain silver bullion at its market valne for silver dollara, United Statea notes or gold coin, or may he purchased hy means of the present hullion fund.

The St. Lawrence Mine.

The El Dorado *Republican* says: It is hardly necessary to say that our mines have been in disrepute for years. The reason for this we have repeatedly explained. One reason is lack of energy and capital on the part of resident holders of the mines to open them. Another is the predominant disposition of those interested in mining property to cry down all claims in which they are not directly interested. But probably the chief reason of our mines heing in bed repute is the successive failures, after the expenditure of large sums of money, although in nearly every case these failures can be traced to incompetency, extravagance, or downright thievery. Mines that have paid hundreds of thousands, and even millions, over working expenses, are closed down for went of means to continue operations when a bad piece is struck, hecause the money has all heen paid in dividends, that is, where it has not all been squendered hy the officers in stock and fast living, and before satisfactory arrengements can he made to continue the work, the mine gets into bad repute and is sold ont for a song. There are half a dozen mines in the county, which, if properly managed, would prove to be as good as any in the State, and among the best of those are the St. Lawrence and Pacific. The time is not distant when these mines will get into the right hands, and the reputation of El Dorado county mines be redeemed. We intend mentioning some of these from time to time, and commence with, hecause it has heen the first in the list to he so redeemed,

The St. Lawrence Mine.

On Friday lest we visited this mine for the first time in about two years. Considering that the works had been closed down for ahout a year, we found everything in much better condition than any one could reasonahly expect, and under the present personal superintendence of H. Rosewan, a man of great experience, good judgment and quick perception, everything is rapidly being put in the best possihle shepe for steady and permanent work. The shaft of the mine is down, on an incline, to the depth of 800 feet, the actnal perpendicular depth beirg about 550 feet. It is a douhle shaft, with double track for care, and a ladder way outside, all timbered in the most substantial manner. The mine hes never heen prospected, the ore heretofore worked hsing nearly all taken from the main shaft, which paid from $8 to $25 per ton. The last work done in the mine hefore it was shut down developed ore tbat would go as high as $75 to $100 per ton. This was at the 800-foot level. Under the new management—A. Mierson and Thomas Alderson, of this city, having the controlling interest in it, men who have heretofore been eminently successful in their undertakings, and whose integrity is unimpeachahle—the shaft is to be extended 200 feet as rapidly as possible. Should the ledge average one-half as well for that distance as it does where work was left off a yeer or more ago, the company will be enabled to pay a dividend or two out of the rock taken from the shaft alone. It is the intention, when this work is accomplished, to hegin sinking a perpendicular shaft nearly due east from the present works and drift hack to the old works, giving them between 600 and 700 feet of solid ore to work through, and in the meantime the old works can be thoroughly prospected and worked out. There can he no doubt that this is one of the hest mines in the State; the parties interested in it, however, are not anxious to have its merits spread before the world at present, preferring to wait and let actual results under economicel and honest management speak for the mine. There is no doubt but that we have got to attein greater depth on sll our quartz mines hefore anything like permanent success can be attained. The St. Lawrence is down the deepest of any mine in the county, and the extent and character of the rook at the lowest level warranta the belief that at a depth 200 feet greeter the mine will prove a reel bonanza.

The mill aud hoisting works are of the very best end most approved mining mechinery. The mill contains 30 stamps, and all of the latest improvements for saving the gold. There is also a first-class saw mill atteched for getting out timbers for the mine. This machinery, together with the buildings as they now stand, cost between $70,000 and $80,000, and conld not be replaced for much less. The works will oe in full operation hefore Octoher, when a force of from 75 to 100 men will be required in various departments, mnkiug St. Lawrenceburg one of the liveliest camps in the county, and when the shipments of treesure fairly begin, trom their magnitude it will he the most noted.

The Reno *Gazette* of Jnne 6th says: A strike waa made in the Bishop mine yesterday at Pyramid lake. Samples of the ore were shown us this afternoon, and they show very well. The noticeahle change is from the yellow chloride on the anrface to the green chloride and copper stain. Old miners will understand the importance of thia change, and competent judges estimate that this ore will assay at least 50 per cent. more than tbe original ledge material. This new ore hody is at least four feet in width, and if these mines keep on improving we will cease talking of ore and confine ourselves to bullion.

A Black hills miner, named J. C. Dodge, was attacked a few daya since by Indians and defended himself till all his cartridges but one had been exhauated and he was about to he taken prisoner, when with it he hlew out his hrains.—*Territorial Enterprise.*

A Prosperous Era in Quartz Mining in Calaveras County.

The Calaveras *Chronicle* says: There has never been so prosperous an era in the quartz mining interests of this county, since the inception of that industry, as at present. There is more life, more energy and activity being evinced than have ever before characterized mining operations, and the result is a very marked and flattering improvement of the condition of mining affairs generally. No other county in the State is advancing so rapidly in the way of mining development as this, and if anything can be judged from the progress being made, the day is not far distant when Calaveras will take the first place in the list of mining counties. In fact, there are a greater number of quartz ledges in process of development in Calaveras to-day than in any other county on the coast, while new enterprises are being constantly undertaken and the field of operations enlarged. The truth of the whole matter is that this county offers better inducements for investment in quartz mining ventures than any other section of the mineral belt, and its advantages are becoming apparent and being appreciated. The whole central portion of the county, from the Mokelumne on the north to the Stanislaus on the south—embracing an area fully 30 miles in length by 12 in width—is literally ribbed with gold bearing veins. The extent of mining country is so large, so much greater than that contained in any other section of equal area, that it is as yet only partially prospected, although there is no lack of paying, permanent, fully developed mines to prove the general good character of the ledges. Within the past year the attention of mining men has been directed to these advantages Calaveras possesses as a favorable locality for operations, and it is to the influx of capital that has followed that the rapid advancement of development is attributable. It is no exaggeration to say that more labor and money have been expended upon quartz lodes and in building mills in this county during the past 12 months than for five years previous, while it is equally true that the great degree of success achieved will stimulate increased activity in the future. For some reason capital fought shy of Calaveras until within the last year or two, and it required the conclusive proof of development, together with a final though tardy appreciation of the fact that for extent, number and richness of its lodes this county stands unrivaled, to induce the co-operation of moneyed men. It used to be said that "Calaveras ledges were all barren," and although the declaration was as false as it was absurd, it exerted an evil influence that retarded development and created a prejudice against the county so deep seated that nothing short of absolute proof to the contrary could up-root it.

The activity and energy at present being displayed, however, together with the flattering prospects for the future, are rapidly making amends for the delinquencies of the past and playing an important part in placing Calaveras where it belongs—at the head of the rank of mining counties. Work is being actively pushed forward in all the principal districts. New ledges are being prospected, abandoned mines reclaimed, mills erected and in fact all the labor consequent upon successful quartz mining is being vigorously prosecuted. The shipments of bullion are steadily increasing, and although the product has yet by no means reached its maximum, it compares favorably with that of any other county and is five times in excess of what it was two years ago.

The improved condition of the quartz mining interest is especially true relative to the northern and eastern portions of the county. In the vicinity of Mokelumne Hill and to the eastward, embracing Glencoe and West Point districts, an unusual degree of activity is observable and gratifying success is being met with.

We give the names of a few of the principal mines in those districts that have within a comparatively short time passed into the hands of capitalists, simply for the purpose of showing with what eagerness men of means are investing in this county: The Enterprise Consolidated and Josephine, at West Point; the San Bruno, Grasshopper and Glencoe Consolidated, at Mosquito; the Quaker City, at Chile Junction; the Lamphear, in Spring gulch, and the Boston, near Buckeye. All of the mines mentioned have lately passed into the hands of incorporated companies and are being systematically worked upon an extensive scale. They are all supplied or being furnished with the machinery necessary for their complete development, and are showing the most favorable indications of proving permanently productive mines. The Gwin, the representative mine of the county, is paying handsome monthly dividends, and other mines still in first hands are also proving largely remunerative. We repeat that the country has never before experienced so prosperous an era in quartz mining, and that the promise of the future is even more encouraging than the realization of the present.

Improved Zinc White.—According to the Austrian chemical society, M. Orr produces a very beautiful zinc white by the following process: Sulphuret of raw barium is washed, and the liquid obtained is mixed with equal quantities of chloride and sulphate of zinc. The precipitate is collected, pressed and dried. It is then heated on a hearth, and, while hot, is thrown into cold water. This last treatment produces a mass of great density, and the material, after washing and grinding, is of great purity and whiteness.—*Scientific American.*

Useful Information.

Testing Oils.

It is very desirable to those in the business to possess the means of testing the oils they buy and sell as lubricants for machinery, and to ascertain whether the same be pure or mixed with some cheaper oil. Unfortunately the simpler tests are few, and such as they are cannot be said to be greatly superior to the judgment derived from the look, taste and smell of the article examined. Various devices are extant to test the lubricating properties of oils, that is, their power of reducing friction to a minimum, but beside being expensive their successful use requires certain knowledge and experience not generally possessed by the dealer. One of these devices consists of a cap over a journal or bearing, and on that is a weighted lever like a scale beam, which presses with a certain weight on the revolving journal. In this cap is a recess in which is inserted the bulb of a thermometer. The ratio between the weight and the heat developed by a certain number of revolutions, with a definite quantity of the oil on the bearing, is an index to the value of the oil.

Other machines are constructed on the same general principle, viz., the generation of friction and the measurement of the heat produced while being supplied with oil. However, in practice we are generally very well able to judge of the lubricating value of an oil by its appearance on a piece of glass, noting its viscosity or cohesion of its particles and its apparent resistance to the touch, and its feeling of smoothness. This is what we call "body" in an oil. As we said, the practical tests as to the purity of an oil are few. For instance, with the petroleums, they all mix in any proportion and the most rigid chemical test would fail to show the admixture of another of the species. We may, however, easily prove the admixture of animal or vegetable or resin oils in petroleum by a very simple test. This is simply by an alkali, and the most ready and convenient is ammonia, or, as commonly called, spirits of ammonia. If lard, whale, or fish oils or resin be present, and a little of the ammonia added, there will be a partial saponification of the mass, which will have the appearance of cream, and in the case of resin the mass will nearly solidify or have the consistence of butter.

To test for foreign or suspended impurities in an oil it is a good plan to take a piece of clean blotting paper and put on it a few drops. The bibulous paper will then absorb the oil and the impurities or particles of sand or free carbon, or whatever they may be, will be left on the surface. These may be seen with the naked eye or a magnifying glass of even feeble power. —*American Manufacturer.*

How to Clean Kid Gloves, etc.—"Laws of Life" gives the following recipe for cleaning kid gloves, etc.: Get gasoline, which can be procured at the drug store at 40 cents a gallon. Lay your glove on a long, flat bottomed dish like a common vegetable dish, and cover it with the gasoline; rub soiled spots with a clean white rag, squeeze, not wring it, with your hand as dry as you can, lay it on clean old muslin, take one corner of the muslin and rub the fingers and thumb out smooth, rub soiled spots if any remain, inflate by blowing into it, then pin on a cloth out-of doors to dry. The process should be gone through very quickly, as the glove is injured by remaining in the liquid; not more than 10 minutes being occupied in cleaning the pair of gloves. This will be found excellent economy. Clean cashmere lace by dipping or rinsing it in the gasoline, being careful not to rub so as to get the meshes and figures out of place. Dry it out of doors, then lay it on a cloth in good form, and place between the leaves of a book to press. If it is desired to whiten unbleached Valenciennes lace, lay it on a cloth and cover with magnesia or baby powder, leaving it over night. Blow off the dust and repeat if need be.

To Remove Spots from Carpets.—Mix half an ox's gall with one quart of water; wet and rub the spot with this. Then, with a clean scrubbing-brush, warm water, and soap, scrub the spot well, and wet and half wring a clean floor-cloth in clean cold water and rub the soap and gall out of the carpet; rub the spot with a dry, coarse cloth until it is nearly dry, then pin a piece of thin brown paper over the spot, to prevent the dust from settling on it while wet, and leave it to become perfectly dry. If the spot occurs near the side or end of the carpet, undo a few tacks and slip under the spot a thickly folded coarse towel to absorb the water which runs through, and prevent the wet carpet from lying in the dust; after washing the spot, remove the folded cloth and slip in its place a piece of brown paper, and leave this till the carpet is perfectly dry.

It is said that leather may be affixed to metal so that it will split before it can be torn off, by means of the following composition: A quantity of nut-galls reduced to a powder is dissolved in eight parts of distilled water, and after remaining for six hours is filtered through a cloth. This decoction is to be applied to the leather. Then take a similar quantity of water and add to it one part (by weight) of glue, which is to be held in solution for 24 hours, and then applied to the metals, which should first be roughened and heated. The leather is then laid upon the metal and dried under pressure.

Paper Blankets.—A suggestion, says the *British Mail*, that has frequently been made in the newspapers that a sheet of brown paper used as a bed covering between or on top of other wrappers, will impart additional warmth and be as serviceable as a blanket, has been acted upon by a Mr. Loder, who has taken out a patent for paper blankets. They are perforated at distances of about four inches, in order to promote the ventilation which the density of the brown paper material interrupts. These paper blankets will be a great boon to the poor, and as they are clean, economical and ready for use in any emergency, they will be acceptable in hospitals, for the supply of which Mr. Loder has already obtained two or three contracts. In schools and private families their cleanliness and comfort will bring them into much service, and in hot climates, where blankets are liable to be infested with insects, these paper coverlets will be found to be very desirable.

Adulteration of Sugar.—A case of adulteration of sugar, recently tried at Marseilles, has excited a good deal of attention there. Fraud of the kind had long been suspected by the customs officials, and the cargo of sugar in the present case was from Reunion. The Reunion sugars of brown hue are very rich in saccharine matter, and well suited for mixture. It was first thought that the sugar had been mixed with pounded bricks and sand, but on analysis the added matter was found to be slag (a sort of opaque glass formed in the working of various metals, or vitreous lava from volcanoes) along with sand, and an economy of 12 fr. per 100 kilos. was anticipated. The slag has a bright granular fracture, so that it makes a very good imitation of sugar. The sand was added to make up the weight.

Fire Proof Suit.—An extraordinary fire-proof suit, invented by a Swede named Oestberg, was recently exhibited in Vienna, in the presence of the Emperor William and several other distinguished personages. One Captain Ahlstrum, clothed in the suit, walked into an immense fire, prepared for the occasion, of wood saturated with petroleum. The account says: "The heat of the fire was so intense that no one else could approach within eighty paces without being burnt or scorched, but the Captain walked around in the glowing pile perfectly undisturbed, leaning on the burning wood, and finally seated himself on the coals." After remaining in the fire a quarter of an hour, the salamander came out perfectly unharmed, and without "the smell of fire upon his garments."

To detect leaks in gas pipes, apply soap suds to the suspected leaky joint. The formation of bubbles will show any escape. This is safer than trying the joint with a lighted match. If the leak occur in the branch of a bracket or chandelier, it is repaired by soldering with plumber's fine solder; if it be a very small one, heat the piece first with a spirit lamp, and fill the aperture with cement.

A Good way to fasten screws that have become loose, is to fill up the holes tightly with cork. Screws and irons so secured will remain perfectly tight, as when put into new wood.

Good Health.

Position in Sleeping.

It is better to go to sleep on the right side, for then the stomach is very much in the position of a bottle turned upside down, and the contents are aided in passing out by gravitation. If one goes to sleep on the left side, the operation of emptying the stomach of its contents is more like drawing water from a well. After going to sleep, let the body take its own position. If you sleep on your back, especially soon after a hearty meal, the weight of the digestive organs, and that of the food, resting on the great vein of the body, near the back bone, compresses it, and arrests the flow of the blood more or less. If the arrest is partial, the sleep is disturbed, and there are unpleasant dreams. If the meal has been recent or hearty, the arrest is more decided, and the various sensations, such as falling over a precipice, or the pursuit of a wild beast, or other impending danger, and the desperate effort to get rid of it arouses us; that sends on the stagnating blood, and we wake in a fright, or trembling, or perspiration, or feeling of exhaustion, according to the degree of stagnation and the length and strength of the effort made to escape danger. But when we are not able to escape the danger, when we do fall over the precipice, when the tumbling building crushes us, what then? *That is death!* That is the death of those of whom it is said, when found lifeless in their bed in the morning: "They were as well as they ever were the day before," and often it is added, and *ate heartier than common!* This last, as a frequent cause of death to those who have gone to bed well to wake no more, we give merely as a private opinion. The possibility of its truth is enough to deter any rational man from a late and hearty meal. This we do know with certainty, that waking up in the night with painful diarrhea, or cholera, or bilious colic, ending in death in a very short time, is properly traceable to a late large meal. The truly wise will take the safer side. For persons who eat three times a day, it is amply sufficient to make the last meal of cold bread and butter and a cup of some warm drink. No one can starve on it, while a perseverance in the habit soon begets a vigorous appetite for breakfast, so promising of a day of comfort.—*Hall's Journal.*

A New Anæsthetic.

Dr. W. Preyer, of Jena, Saxony, has repeatedly found that a concentrated solution of lactate of soda in water, administrated as a hypodermic injection, or in sufficiently large quantities introduced in an empty stomach, causes a sensation of fatigue and sleepiness perfectly similar to that of a natural sleep, provided, of course, that no disturbance of the senses is applied to keep the person awake. Similar symptoms show themselves after the drinking of large quantities of fresh milk, and more so of milk which has become slightly acid, also of buttermilk either sweet or acid, and even of concentrated sugar-water. The sleep thus produced shows itself sooner among young animals than old ones; more among those which have a more excitable reflex nervous disposition than among those in which it is weaker; among rats, cats, pigeons and frogs sooner than among rabbits and marmots; it also shows itself sooner in small animals than in large ones, and sooner during cold than during warm weather.

Man is very variously affected by lactate of soda; some experience an uncontrollable somnolence after having in the morning, on an empty stomach, drank a glass of thick milk or concentrated sugar-water, or a solution of half an ounce of sugar in four ounces of water; but others will feel no effect. Dr. Preyer thinks that the effects of the lactate of soda deserve to be experimented upon as an antipyretic, as a sedative in mania and certain forms of convulsive affections, on account of the promptness with which it produces muscular relaxation. Every time he observed hypnotic effects of this salt, he found that the respiration became slower and deeper, the irritability diminished, and that, at least among cold-blooded animals, the temperature went down under the influence of strong doses, which are well supported, without ever leaving any inconvenient result. *Exchange.*

Defective Plumbing.—Dr. Robinson, the medical officer at Dover, has recently called attention to the serious results arising from defective plumbing. As an instance of this he says a family had been made ill by a joint of the water pipe having been repaired with white lead, while the cistern, which had also been packed with the same dangerous material, had been used before properly dry. In another case he mentions a family had been poisoned by water from a tank placed under a bed-room floor, the water having been contaminated by the overflow pipe being connected with a foul sewer. It is astonishing to find such gross neglect of well-known sanitary principles, and we fear the only remedy will be to compel builders to submit every plan of a new building, alteration, or repair, to properly qualified authorities, and to make any breach of such a duty a serious offence, punishable by law. We know this is theoretically done now, but it is only in theory, for it is a well-known fact that our water and sewer arrangements are practically done anyhow, just to serve the whim of an individual and effect the saving of a few shillings expense. In short, speculative building is a great curse at the present time, but tenants are themselves much to blame for not properly ascertaining how houses are drained, and how the water is connected, before taking a house to live in.

Grapes in Fever.—Dr. Hartsen, in *Centralblatt fur die Med. Wissenschaften*, recommends grapes as a valuable diet in fever. The grape contains a considerable amount of hydro-carbonaceous matter, together with a certain quantity of potassium salts, a combination which does not irritate, but on the contrary soothes the stomach, and consequently is used with advantage, even in dyspepsia. While considering the carbo-hydrates contained in the grape, we must not neglect the organic acids, particularly tartaric acid. Dr. H. thinks the nourishing influence of these acids too much neglected. It is indeed known that they are changed to carbonic acid in the blood, and are excreted as carbonates in the urine. Possibly careful research might show that, under some circumstances, the organic acids are changed to fats. Dr. H. believes that the organic acids should be ranked with the carbohydrates as food. When fresh grapes are not to be had, raisins or diluted wine might be used.

How to Check Coughs.—Dr. Brown-Sequard, in his late Boston lectures, says that there are many facts which show that morbid phenomena of respiration can always be stopped by the influence of arrest. Coughing, for instance, can be stopped by pressing on the nerves of the lip in the neighborhood of the nose. A pressure there may prevent a cough when it is beginning. Sneezing may be stopped by the same mechanism. Pressing in the neighborhood of the ear, right in front of the ear, may stop coughing. It is also preventive of hiccough, but much less so than of sneezing or coughing. Pressing very hard on the top of the mouth inside is also a means of stopping coughing. And he adds that the will has immense power there. There was a French nurse who used to say, "The first patient who coughs here will be deprived of his food to-day." It was exceedingly rare that a patient coughed then.—*Baltimore Physician and Surgeon.*

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

Four weeks are rated a month.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving to our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

DOUBLE SHEET ISSUE—24 PAGES.

San Francisco:
Saturday Morning, July 1. 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Centennial Fourth; Operating Hydraulic Nozzles, Page 1. A New Volume; Heavy Machinery for the Comstock; The Title-Deed of Our Liberties, 8-17. Then and Now; The Celebration in this City; Notices of Recent Patents, 17. California; The President's Centennial Proclamation; Our Antipodes; Patents and Inventions, 20.

ILLUSTRATIONS.—Centennial Bells, 1. Reading the Declaration in 1776, 8. A California Harvest Scene, 9. "Let Music Swell the Breeze;" Just a Possible Effect of the Cincinnati Convention, 10. A Ringing Declaration; The American Eagle, 11. Sham Battle and Grand Naval Bombardment in S. F. Harbor, July 3d, 1876, 12-13. "One Hundred Years Ago," 17.

CORRESPONDENCE.—Some of the Mines of El Dorado County; Overland Chat, 2-6.

MECHANICAL PROGRESS.—The Whitby Jet Manufacture; He Valued his Machine Higher than his Title; The Mikado's Coach; High Pressure Steam; Mechanical Value of the Diamond; Hair Cloth; Care in Handling Machinery, 3.

SCIENTIFIC PROGRESS.—Newly Discovered Mechanical Action of Violet Light; Fibrous Puddled Iron; Mechanical Equivalent of Heat; The Root-Cap of a Plant; The "Pandora" Arctic Expedition; Success of Zinc as an Anti-Incrustator; Science in Brazil, 3.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 4.

MINING SUMMARY from various counties in California, Nevada, Idaho, Oregon, Montana and Utah, 5.

THE ENGINEER.—A Railroad to go Across the Eastern Continent; The Flooding of the Sahara; A New Drawbridge; The Pneumatic Railway in Paris; The East River Bridge; Multiple Drilling Machine; Results of Captain Eads' Work; Another Ship Canal Project; Monolithic Aqueduct; Engineers in Her Majesty's Service, 6.

USEFUL INFORMATION.—Testing Oils; How to Clean Kid Gloves, Etc.; To Remove Spots from Carpets; Paper Blankets; Adulteration of Sugar; Fire Proof Suit, 7.

GOOD HEALTH.—Position in Sleeping; A New Anæsthetic; Defective Plumbing; Grapes in Fever; How to Check Coughs, 7.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 20 and other pages.

MISCELLANEOUS ARTICLES.—The New Silver Bill; The St. Lawrence Mine, 6. California Harvest Scene—Dr. Glenn's Farm in Colusa County; Electricity Against Gas; Pyramid Lake Mines, 9. The Fourth in Philadelphia; The First Declaration; Ventura County; Jefferson's Marriage; Franklin in Philadelphia; Averill Chemical Paint, 10. The Judges at the Centennial; Off for Philadelphia; Who'll Till Our Fields a Hundred Years from Now (Poetry), 11. The Fourth of July in San Francisco; An Early Celebration; At the Centennial, 12-13 The Celebration in New York; A Centennial Tribute (Poetry); A Little Centennial Expedition, 13.

NEW ADVERTISEMENTS.

Giant Powder, Bandmann, Nielsen & Co., General Agents, S. F.; Cameron's Steam Mining Pumps, Neylan & Young, Agents, S. F.; Buffalo Excelsior Pony Planer and Matcher, Geo. Parr, Buffalo, N. Y.; Deetken's Roasting Furnace, G. F. Deetken, Grass Valley, Cal.; Excelsior Scroll Saw—Latest Improvement, Geo. Parr, Buffalo, N. Y.; Union Con. Silver Mining Co.—Meeting; Assay Office and Chemical Laboratory, Thos. Price, S. F.; Umpire Tunnel and Mining Company of Utah—Assessment.

PRISMOIDAL ROAD AT SONOMA LANDING.—On Monday last the work of building a prismoidal railroad from the steamboat landing on Sonoma creek to the town of Sonoma was begun. The experiment will be limited to a section of two miles. If this section shall work satisfactorily, when finished, the road will be extended to Sears' point, and from there to the town of Sonoma. From Sonoma it is intended eventually to build it to Santa Rosa, the ultimate terminus.

A New Volume.

With the present number we commence Volume XXXIII of the MINING AND SCIENTIFIC PRESS. In thus entering upon a new term it is needless to inform our patrons that the PRESS has kept full pace with the general prosperity which has attended mining operations of late throughout the Pacific coast, and that we take a just pride in recording, year after year, fresh evidences of success in our efforts to furnish our readers with a first-class industrial journal for the progressive people of this coast. As a special evidence of our desire to keep fully up with the times and to make good our intent, we call special attention to the twenty-four page edition of to-day. Realizing that the miners and mechanics are as patriotic as other classes of the community, we have prepared, at considerable expense, a number of appropriate illustrations and timely articles in keeping with the Centennial year and "the day we celebrate." This must, moreover, be our excuse for omitting our usual mining and mechanical engravings; but as the Centennial does not come very often we trust our readers will appreciate our efforts to furnish an appropriate paper for the times.

For the future, we have only to say that we will continue, as in the past, our utmost endeavors to make the PRESS all that is desirable as a medium for the collection and dissemination of whatever can be made useful in advancing the mining, mechanical and general interests of the Pacific coast. While laboring faithfully and industriously in our chosen field we owe our patrons and readers many thanks for the unmistakable evidences of appreciation with which they have received our efforts.

It will still, as heretofore, be our aim to stimulate all honorable enterprises, to raise a warning voice against all wild and reckless speculations, to record passing events, to marshal in appropriate order all the important discoveries and suggestions of the day, whence our readers may extract lessons of wisdom, whether in the paths of science or industry. Our journal becomes, in this way, with its faithful record of all that is useful or instructive, indispensable to the miner, mechanic or artisan, and a work of reference which will be sought for in every library.

We will, of course, continue to uphold the mining interests of the coast in every proper way. That is, the contents in this connection will be such that they can be relied on without reservation. Unswerving from what we believe to be the truth, we will at the same time act liberally, but without prejudice. There is something above mere money making to be looked to, for we are not working for any temporary objects, but intend to build up a paper allied with the permanent interests of the country. It may not be pecuniarily profitable to us individually, but we hope to keep up a paper which will be an honor to those we represent.

We hope, however, to have what assistance is possible to this end from all lovers of science, mechanics and mining. Many of our subscribers could easily aid us and others in their calling by occasionally writing for the PRESS on appropriate topics. We will treat the efforts of all with respect, and the writers be sure to receive a reward they cannot be cheated out of—a consciousness that they have been of assistance to others.

We trust it is needless to urge upon our readers the necessity of promptly renewing their subscriptions. The paper speaks for itself by the character and variety of its contents. Everything that untiring industry and reasonable expense can accomplish will be done to render the MINING AND SCIENTIFIC PRESS a journal which shall be creditable to the interests it represents, and of special value to its large circle of industrial and progressive readers.

Heavy Machinery for the Comstock.

Messrs. Parke & Lacy, 417 Market St., agents for the Burleigh drilling appliances, and for general mining machinery and machinists' tools, are just shipping a lot of heavy articles up to the Comstock. Among them is a large lathe—seven foot swing and 22 foot bed—for George Emmet's Gold Hill foundry. There is also a 48 foot planer, 16 foot bed for the same foundry. Parke & Lacy are also shipping two Burleigh drills, and a large No. 4 air compressor for the Ward mine. The superintendent of this mine says he is going to sink the shaft quicker than any similar work has been performed on the Comstock lode. With this object in view, he has purchased the heavy machinery referred to. The progress of the shaft will be watched with interest by mining men. An air compressor and tank are also being sent to the Julia mine. The shaft in the Julia is the deepest on the lode. The mine has already several Burleigh drills and a compressor, and the pumping and hoisting machinery is of a capacity to work to a depth of 2,500 feet. The present compressor furnishes air to the mine and three sets of drills, but the new compressor and tank are required for an additional supply of air.

READING THE DECLARATION IN 1776.

THE FOURTH ON MT. DAVIDSON.—A large beacon fire is to be lighted on top of Mount Davidson, Nevada, on the night of the Fourth of July. The beacon fire will be visible from all parts of Virginia, also Gold Hill, Silver City, Dayton, Washoe valley, Carson valley, Genoa and all the surrounding country east of the Sierra Nevada range. It is estimated that the beacon light will be seen for a distance of 200 miles.

GOLD has been discovered at Calpella, in Mendocino county, and a company formed for the purpose of working the claim.

The Title-Deed of Our Liberties.

The Declaration of Independence and Many Interesting Facts Concerning It.

The Independence of the United States dates from the Fourth day of July, 1776, and the glories of this Centennial year culminate on the hundredth anniversary of that day, July 4th, 1876. The great event of the day one hundred years ago was the formal signing of that grand document known as the Declaration of Independence. It is appropriate to the present to refresh our memories concerning the sterling deeds of that early time and to fill our minds with double weight of the reverence and rejoicing with which we have been taught from childhood to greet the coming of the nation's birthday.

To aid our readers to this patriotic sentiment we reprodnce the grand, ringing sentences which compose the instrument which gave form and unity to the revolutionary effort, and mention many interesting facts concerning it which recent research has brought to light.

The Declaration of Independence.

On another page we print the declaration with the type woven into the outline of the historic "Liberty bell" which rang out its adoption to a waiting people.

How the Declaration Was Written.

For the following interesting facts concerning the Declaration we are indebted to a timely and well written article in *Scribner's Magazine* for July, reviewing the historical facts which led to the Declaration. As is generally known, the Declaration was written by Jefferson. He was unsurpassed in his time in power of expression. He accordingly framed it; Franklin and Adams suggested a few verbal amendments; Sherman and Livingston had none to offer, and the document stood ready to be reported to the Congress.

Some of those who throng to Philadelphia this summer may feel an interest in knowing that the "title-deed of our liberties," as Webster called it, was written in "a new brick house out in the fields"—a house still standing at the south-west corner of Market and Seventh streets, less than a quarter of a mile from Independence square. Jefferson had there rented a parlor and bedroom, ready furnished, on the second floor, for thirty-five shillings a week; and he wrote the Declaration in this parlor, upon a little writing-desk, three inches high, which still exists. In that modest room we may fancy Franklin and Adams listening critically, Sherman and Livingston approvingly, to what was for them simply the report of a committee. Jefferson had written it, we are told, without the aid of a single hook; he was merely putting into more systematic form a series of points long familiar.

Signing the Document.

Jefferson used to relate, "with much merriment," says Parton, that the final signing of the Declaration was hastened by a very trivial circumstance. Near the hall was a large stable, whence the flies issued in legions. Gentlemen were in those days peculiarly sensitive to such discomforts by reason of silk stockings; and when this annoyance, superadded to the summer heat of Philadelphia, had become intolerable, they hastened to bring the business to a conclusion. This may equally well refer, however, to the original vote; flies are flies, whether in July or August.

American tradition has clung to the phrases assigned to the different participants in the scene: John Hancock's commentary on his own bold handwriting, "There, John Bull may read my name without spectacles;" Franklin's, "We must hang together, or else, most assuredly, we shall all hang separately;" and the heavy Harrison's remark to the slender Elbridge Gerry, that, in that event, Gerry would be kicking in the air long after his own fate would be settled. These things may or may not have been said; but it gives a more human interest to the event, when we know that they were even attributed. What we long to know is, that the great acts of history were done by men like ourselves, and not by dignified machines.

Reading the Declaration.

On the fifth day of July, Congress sent out circulars announcing the Declaration. On the sixth the document appeared in a Philadelphia newspaper and on the eighth it was read by John Nixon in the yard of Independence hall, as shown in our illustration. Before the reading, the king's arms over the door of the supreme court room in Independence hall were torn down, and these trophies were burned in the evening in the presence of a great crowd and amid the joyful pealing of the old Independence bell.

Facts About the Signers.

Even those who look with the greatest pride and hope upon the present and future of this nation, must admit that the Continental Congress contained in 1776 a remarkably large proportion of able and eminent men. The three most eminent delegations naturally were from what were then the three leading States—Virginia, Massachusetts and Pennsylvania. Virginia contributed Thomas Jefferson, who framed the Delaration; Richard Henry Lee, whose resolutions preceded it; Francis Lightfoot Lee, his brother; Wythe and Braxton, who had stood by Patrick Henry in the old House of Borgesses; Nelson, who had first proposed organizing the Colonial militia of Virginia, and who

California Harvest Scene—Dr. Glenn's Farm in Colusa County.

We present on this page an engraving drawn from the oil painting of Andrew P. Hill, painted for G. W. Hoag, representing a "California Harvest Scene." It will give those at a distance a good idea of the magnitude with which agricultural operations are carried on in this State.

It is peculiarly a California scene. The immense separator and the engine to drive its hungry jaws and rattling beaters and shelving screens, the ever widening circle of the headers and header wagons, the mules dragging away the quickly accumulating straw, the owner in his carriage and the overseer on horseback supervising the small army of men required to do the work, the bright sunlight flooding the scene—all these are characteristics of our peerless harvest scenes.

The scene is laid on the magnificent property of

Dr. Hugh J. Glenn,

In Colusa county. As Dr. Glenn is one of our farmer princes, it is interesting to note the steps by which he reached his success and gained his fine estate. Dr. Glenn was born in Augusta county, Virginia, Sept. 18th, 1824. In 1831 his father moved to Paris, Missouri, and Hugh went to school, finishing a good common school education at the age of 17. In 1843 he passed a season behind the counter of a dry goods store and afterwards studied medicine, finishing his medical reading in 1846. At the breaking out of the Mexican war Dr. Glenn served under Sterling Price, returning in 1847 to resume his medical studies under Prof. McDowell, at the State medical university of Missouri. In the spring of 1849 the doctor received his diploma, and returned home, as he says, "to fulfil a contract with a certain young lady, made some seven years prior to that event." He was married on the 13th of March, 1849, to Miss Nancy H. Abernethy.

When Dr. Glenn married he had but $110, with which he purchased a quarter interest in an ox team, consisting of four yoke. On the 3d of May following he left the Missouri river for California, with the ox team. He arrived in Sacramento in the latter part of August, 1849, and camped near or on the site of the Golden Eagle hotel. Dr. Glenn went to the mines, where he was successful. After a few months he sold out his claim, and bought some teams and freight wagons, and followed teaming until he met with an opportunity of selling out with a handsome profit. Then he bought a lot and put up a livery stable in Sacramento, which he sold soon at a good profit. On the 9th of June, 1850, he returned to Missouri. He says, "at that time I had $5,000, and felt richer than I ever have since, or ever shall, though I may be worth millions." From 1852 until the breaking out of the great rebellion Dr. Glenn was engaged in buying and selling horses and mules, and driving them to California and the Southern States.

Dr. Glenn made his first purchase of the Jacinto grant in December, 1867. He has now 45,000 acres under cultivation. He farms 15,000 acres himself, and rents 10,000 acres to G. W. Hoag, 10,000 acres to Pike Gupton, and 10,000 acres to Isaac Bayless. He has on his property 150 miles of fence. The average yield of wheat on these lands has been 25 bushels per acre in favorable seasons. Of this year's crop Dr. Glenn says although he has on hand 325,000 (140 lb.) sacks, he thinks they will not hold the wheat.

George W. Hoag.

On his 10,000 acre farm, Mr. George W. Hoag has everything arranged for complete independence in farming operations. He has his own machine shops, blacksmith shops, boring, turning and planing machines, buzz saws, etc. He manufactures his own wagons, separators, headers, harrows and nearly all the machinery and implements used. Perhaps we cannot give a better idea of the magnificent breadth of this establishment than by enumerating some of the leading items of men, animals and implements employed. He has employed about 45 men in seeding and 100 in harvest. He has also 200 header horses and mules; 55 grain headers and other wagons; 25 eight-mule gang plows; 21 eight-mule harrows; 100 sets of harness; 10 12-foot headers; three sulky hay rakes; nine eight-mule cultivators; two Gem seed sowers; four Buckeye drills; six mowers; one 48-inch separator, 36 feet long and 13½ feet high, when mounted, capacity 10 bushels per minute; one 40-inch separator, 36 feet long; two 40-foot elevators for self feeder; one steam barley or feed mill; two 18 horse-power engines.

The Monitor Separator.

A prominent feature in Mr. Hill's painting and in our engraving is Mr. Hoag's mammoth separator, the "Monitor." The "Monitor" is a combination of the "Pitts," "Geyser," and "Vibrator" machines, and was built at Mr. Hoag's shops, on the Glenn farm, under his supervision. This separator threshed on the 8th of August, 1874, 5,779 bushels of wheat. The machine is represented in active operation in the picture, and we give for the benefit of many of our readers who are not familiar with such a scene the following brief description of the threshing: First the "circle" is made. It is the starting point in the field where the machinery is placed. The "circle" is made by the headers in advance of the separator and engine. After the grain is cut from the "circle," which usually embraces a space of 100 to 125 acres, the separator and engine are drawn in and the work of threshing commences. The working force to run the machine is 56 men, 7 headers, 21 header wagons, 96 horses or mules. The average run of the machine is 1,700 sacks, containing 2¼ bushels each per day. The utmost capacity of the machine is 3,000 sacks, or 6,750 bushels per day. The harvesting force cut and thresh simultaneously, and in fifteen minutes from the time the header begins in the grain, the wheat is in the sacks.

Such in brief are the facts connected with the scene which we present to our readers. In the breadth and scope of its representation the picture is symbolic of our California agriculture. It is the embodiment of enterprise, of action and of success. It is a stirring scene. It is fitting to awaken among our friends abroad a new appreciation of what may be styled the magnificent in our agriculture.

It is but justice to Mr. Hill to state that in the necessary space of a newspaper illustration his painting is much condensed and the effects of the branches are but feebly reproduced.

[Copyrighted and published by permission.]

A CALIFORNIA HARVEST SCENE.

Electricity Against Gas.

The Great Northern railway company of France has undertaken a series of experiments which seem to indicate the approach of a great revolution in the mode of lighting public buildings and thoroughfares. To judge from the reports recently published, electricity seems destined to eclipse gas altogether. A few weeks ago a three-horse power Gramme machine was employed to light the luggage department of the Paris Great Northern railway station. This room or hall measures 20,000 cubic feet and is generally illuminated by twenty-five gas burners. The new electric light was placed at a distance of ten meters from the ground, and gave a light of a peculiarly soft character, which renders the use of the full globe employed to check the irritating glare of gas quite unnecessary—a fact of some importance, as it tends to augment the economy realized by the new system. The light continued to burn the whole evening with great regularity, excepting, of course, when it was purposely lowered. The success attained was so conclusive, if we may believe accounts, that the company intend illuminating the vast structure, containing 300,000 cubic meters of space, where the trains arrive, by the same process. For this purpose electric lanterns, if we may so call them, of exceptional power, will be placed at a hight of twenty meters. They will be placed at the four summits of a rectangle, so there will be no shade or dark corner in the whole edifice. The goods station at La Chapelle will also be lighted in a similar manner.

M. Tresca, an energetic advocate of the electric system, has been able at last to estimate the amount of power required to produce a given quantity of light by the magneto-electric machines. In this respect former experiments had been eminently unsatisfactory, and M. Tresca gives an exhaustive description of all the difficulties that had to be surmounted, in a report which is inserted in the minutes of the Academy of Sciences. The results have been obtained chiefly from two machines—the first giving a light equivalent to 1,850 carcel burners, that consume 40 grammes of oil per hour, and the second equal to 302 similar burners. With the former it is easy to read at a distance of 21.50 m., and with the latter at 7.70 m. The reflection also from the walls is so strong that persons can read at these distances, even when holding the book with its back to the light. From a lamp equal to 100 burners the same result can be obtained at a distance of five meters. Four electric lamps of this power have been in use during the last year in the factory of Messrs. Hellman, Ducommon & Steinlen, of Mulhouse, and give a satisfactory light over an area of 1,850 square meters. The most important and crowning fact, however, is the assertion that the electric light is 100 times less expensive than oil, and 50 times cheaper than gas. Should a prolonged and practical application of the new system prove this startling comparison to be correct, we may look forward to a great change, which will ultimately compel the gas makers to, at any rate, make a great alteration in their scale of charges, if it should not interfere even more seriously with their interests.—*The Builder.*

Testing Oils.

It is very desirable to those in the business to possess the means of testing the oils they buy and sell as lubricants for machinery, and to ascertain whether the same be pure or mixed with some cheaper oil. Unfortunately the simpler tests are few, and such as they are cannot be said to be greatly superior to the judgment derived from the look, taste and smell of the article examined. Various devices are extant to test the lubricating properties of oils, that is, their power of reducing friction to a minimum, but beside being expensive their successful use requires certain knowledge and experience not generally possessed by the dealer. One of these devices consists of a cap over a journal or bearing, and on that is a weighted lever like a scale beam, which presses with a certain weight on the revolving journal. In this cap is a recess in which is inserted the bulb of a thermometer. The ratio between the weight and the heat developed by a certain number of revolutions, with a definite quantity of the oil on the bearing, is an index to the value of the oil.

Other machines are constructed on the same general principle, viz., the generation of friction and the measurement of the heat produced while being supplied with oil. However, in practice we are generally very well able to judge of the lubricating value of an oil by its appearance on a piece of glass, noting its viscosity or cohesion of its particles and its apparent resistance to the touch, and its feeling of smoothness. This is what we call "body" in an oil. As we said, the practical tests as to the purity of an oil are few. For instance, with the petroleums, they all mix in any proportion and the most rigid chemical test would fail to show the admixture of another of the species. We may, however, easily prove the admixture of animal or vegetable or resin oils in petroleum by a very simple test. This is simply by an alkali, and the most ready and convenient is ammonia, or, as commonly called, spirits of ammonia. If lard, whale, or fish oils or resin be present, and a little of the ammonia added, there will be a partial saponification of the mass, which will have the appearance of cream, and in the case of resin the mass will nearly solidify or have the consistence of butter.

To test for foreign or suspended impurities in an oil it is a good plan to take a piece of clean blotting paper and put on it a few drops. The bibulous paper will then absorb the oil and the impurities or particles of sand or free carbon, or whatever they may be, will be left on the surface. These may be seen with the naked eye or a magnifying glass of even feeble power. —*American Manufacturer.*

Care in Handling Machinery.—The general thoughtless handling of machines, cleaning parts of machines while in motion, adjusting parts which should be at rest while being acted on, and other habits contracted by familiarity, should be avoided. A machine ought not to be trifled with. It has no remorse or pity. Once in its power, there is no escape. It should be managed with caution and constant care, for in dealing with machinery it is always better to be foolishly careful than carelessly foolish.

The Fourth in Philadelphia.

A dispatch from Philadelphia furnishes interesting information of the way the nation's birthday will be celebrated in the "Cradle of Liberty." The ceremonies will take place at Independence hall, beginning at an early hour with a review of the military from in front of the hall on Chestnut street. A stand, capable of accommodating 100 to 150 persons, is being erected for the purpose. The literary exercises, under the auspices of the United States Centennial Commission, will take place in the square immediately in the rear of Independence hall, where a platform of sufficient capacity to accommodate some 4,500 persons, among whom will be the guests of the city, musicians, etc., will be provided. The exercises will commence immediately after the termination of the military review, at about 10 o'clock, and will be initiated by the Right Rev. Bishop Simpson, the ecclesiastic successor of the chaplain of the Continental congress.

Overture, "The Great Republic," by George T. Bristow, of New York, member of the jury on Musical Awards.

Chorus.

Reading of the Declaration of Independence from the original document by Richard Henry Lee, of Virginia, grandson of the mover of the Declaration.

Hymn of welcome, by Oliver Wendell Holmes, written to the music of Keller's hymn—orchestra and chorus.

National ode by Bayard Taylor.

Greeting from Brazil—a hymn composed at the request of his Majesty, Dom Pedro, Emperor of Brazil, by the distinguished Brazilian, Carlos Gomez, and dedicated to the American people.

Oration by William M Evarts.

Hallelujah—Orchestra and chorus.

Doxology—"Old Hundred."

Gilmore will be given charge of the orchestra, with Carl Zentz as chorus master.

The period to be covered by the programme is estimated not to exceed three hours. Invitations to witness the demonstrations of the evening of the 3d, and to participate in the observances of the 4th, have been sent by General Hawley to Governors of all the States and Territories of the Union, and from several, assurances of their intention to be present have been received.

The First Declaration.

Before the document known as the Declaration of Independence was adopted, the Continental Congress, in the earlier months of 1776, had for many days been steadily drifting on toward the distinct assertion of separate sovereignty, and had declared it irreconcilable with reason and a good conscience for the colonists to take the oaths required for the support of the Government under the crown of Great Britain. But it was not till the 7th of June that Richard Henry Lee, of Virginia, rose and read these resolutions:

"That these United Colonies are, and of right ought to be, free and independent States; that they are absolved from all allegiance to the British crown, and that all political connection between them and the State of Great Britain is and ought to be, totally dissolved.

"That it is expedient forthwith to take the most effectual measures for forming foreign alliances.

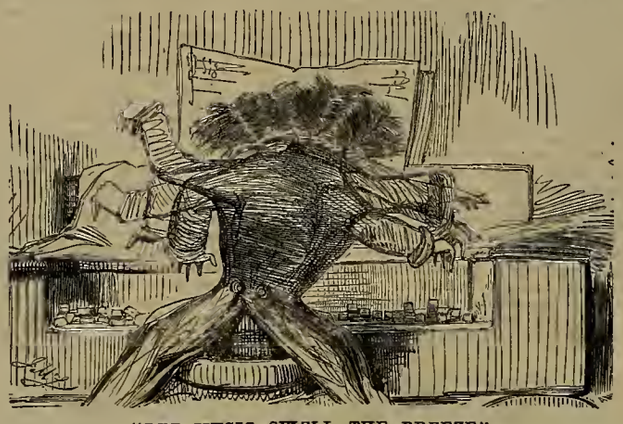
"That a plan of confederation be prepared and transmitted to the respective colonies for their consideration and approbation."

These resolutions were presented under direct instructions from the Virginia Assembly, the delegates from that colony selecting Mr. Lee as their spokesman. They were at once seconded, probably after previous understanding, by John Adams, of Massachusetts, Virginia and Massachusetts being then the leading colonies. It was a bold act, for it was still doubtful whether anything better than a degrading death would await these leaders, if unsuccessful. These resolutions were debated from time to time until the second day of July, when they were adopted by the vote of 12 colonies. New York, though not voting, ratified the vote by a convention within a week. The Declaration of Independence was then written.

VENTURA COUNTY.—Mr. McArthur writes to us that he mailed some time since a manuscript of notes taken during his tour through Ventura county. They never reached us. We hope Mr. McArthur will reproduce them for us.

Jefferson's Marriage.

The affair was quite a little comedy in some aspects, and ended as all comedies should, with everybody made happy. "Belinda" had been married many years, and her old admirer was approaching 30, when he met with a young lady of 22 who produced a strong impression upon him. She was a little above the medium hight, slender, but elegantly formed. A fair complexion, with a delicate tint of the rose, large hazel eyes, full of life and feeling, and luxuriant hair of a rich soft auburn, formed a



"LET MUSIC SWELL THE BREEZE"

combination of attractions which was eminently calculated to move the heart of a youthful bachelor. In addition to all this, the lady was admirably graceful: she rode, danced, and moved with elegant ease, and sang and played on the harpsichord very sweetly. Add still to these accomplishments the possession of excellent good sense, very considerable cultivation, a warm heart, and a considerable fortune, and it will not be difficult to understand how the youthful Mr. Jefferson came to visit very frequently at the lady's residence, in the county of Charles City. It was called "The Forest," and the name of the lady was Mrs. Martha Skelton. She was a daughter of John Wayles, an eminent lawyer, and had married in her 17th year, Mr. Bathurst Skelton, who, dying in 1768, left his young wife a widow at 19. As the three years of mourning began to expire, the beautiful young lady found herself besieged at "The Forest" by numerous visitors. Of these, three were favorites with the fair Mrs. Skelton, of whom Mr. Thomas Jefferson was one. The tradition runs that the pretensions of the rivals were decided either by the musical accomplishments of the young counselor or by the fears of his opponents. The tale is differently related. One version is that the two unfortunate gentleman encountered each other on Mrs. Skelton's door-step, but hearing Jefferson's violin and voice accompanying the lady in a pathetic song, gave up the contest thenceforth, and retired without entering, convinced that the affair was beyond their control.

The other story is that all three met at the door and agreed that they would take their turns. Jefferson entered first, and the tones of the lady in singing with her companion deprived the listeners of all hope. However this may be, it is certain that the beautiful widow consented to become Mrs. Jefferson, and on the first day of January, 1772, there was a great festival at "The Forest." Friends and kindred assembled from far and near; there was frolicking and dancing after the abundant old fashion; and we find from the bridegroom's note-book that the servants and fiddlers received fees from his especial pocket. It snowed without, but within all was mirth and enjoyment, in the light and warmth of the great log fires roaring in honor of the occasion. Soon after the performance of the ceremony, the bridegroom and his bride set out in their carriage for "Monticello," where Jefferson had commenced building in 1769, just before the destruction by fire of his patrimonial house of "Shadwell." The journey was not to end without adventures. As they advanced toward the mountains the snow increased in depth, and finally they were compelled to leave the carriage and proceed upon their way on horseback. Stopping to rest at "Blenheim," the seat of Colonel Carter, where they found, however, no one but an overseer, they left it at sunset, resolving bent upon reaching Monticello that night. It was eight miles distant, and the road, which was rather a mountain bridle-path than an honest highway, was encumbered with snow three feet deep.

We may fancy the sensations of the newly wedded bride at the chill appearance of the desolate landscape as she passed along through the snow; but she was a woman of courage and good sense, and did not care for inconvenience. It was late when they arrived, and a cheerless reception awaited them—or rather there was no reception at all. The fires were all out, the servants had gone to bed, and the place was as dark and silent as a grave. Conducting his wife to the little pavilion which was the only part of the house habitable at the time, Jefferson proceeded to kindle a fire and do the honors. On a shelf behind some books part of a bottle of wine was discovered; and this formed the supper of the bridegroom and the bride. Far from being annoyed or discomforted by their reception, however, it only served for a topic of jest and laughter. The young lady was as light-hearted as a bird, and sent her clear voice ringing through the dreary little pavilion as gayly as she had ever done in the cheerful drawing-room of "The Forest;" and thus the long hours of the winter night fled away like minutes, winged with laughter, merriment, and song.—*Harper's Magazine for July.*

Franklin in Philadelphia.

The advent of Franklin into the city on the day when, a shabby lad of 17, he walked up High street munching his roll, really marks the date of the birth of the intellectual life of Philadelphia. There is not an effort for her improvement, mental or practical, which cannot be traced to its origin in the teeming brain of the energetic printer. Schools, universities, free churches, public libraries, drainage, fire and military companies, street lamps and street sweepings—every reform, from the broad policy of the statesman to the smallest detail—bears somewhere the bold scrawl, Franklin *fecit*. The wisdom and scholarship of that day were wholly drawn from books. Franklin dealt directly with the great natural forces, physical and human; out of the unlikely material of his fellow-apprentices he made the philosophic junto; with the petty politics of the drowsy town, he studied statecraft; a kite and key under his keen eyes told the secret of the lightnings, which secret had been kept for ages. Nothing was too insignificant for the life-giving glances of those keen eyes. He sees a seed adhering to the straws on his wife's besom, plants, tends it, and gives to the country the before unknown broom corn and a new source of industry. He observes a green twig on a basket lying on the wharf, thrown from an Amsterdam brig, plants and tends that, and presently Pollard willows grow wild by every stream. He is the foremost typical American in our history; moral rather than religious; a domestic man; faithful to his wife, yet cultivating platonic friendship with other women; never losing his self control, yet with a keen, fine sense of fun; testing, one minute, a high metaphysical problem, and, the next, a counterfeit dollar; always master of the present moment whether it demanded the making of cases, roller and ink, which he had no money to buy, or the construction of a new government from the ruins of the old.—*June Scribner's.*

JUST A POSSIBLE EFFECT OF THE CINCINNATI CONVENTION.

The Constitution confers upon Congress the sovereign power over the Territories of the United States for their Government, and the exercise of this power. It is the right and duty of Congress to prohibit and extirpate in the Territories that relic of barbarism, polygamy, and we demand such legislation as shall secure this end and the supremacy of American institutions in all the Territories.—*Cincinnati Platform, June 15th, 1876.*

THE NEW BELL FOR INDEPENDENCE HALL.—The new bell for the Pennsylvania State House weighs 13,700 pounds, and is seven feet high and 23⅛ feet in circumference around the lip; the clapper weighs 300 pounds and the hammer more than 200 pounds. Its material is a mixture of 80 per cent. copper and 20 per cent. tin; cannon captured from the British at Saratoga, in the Revolutionary war, and bronze guns disabled at Gettysburg are represented in this monster bell. The old bell weighed only 6,400 pounds. For weeks workmen have been strengthening the belfry with stout timbers, and experts say that it will safely stand the new weight. The bell was presented to the city by Henry Seyhert, who also put in a new clock, with dials nine feet in diameter, at a total cost of $20,000. The bell bears the modest inscription: "Presented to the city of Philadelphia, July 4th, 1876, for the belfry of Independence hall, by a citizen." Around the lip is the motto, "Proclaim liberty throughout all the land unto all the inhabitants thereof," and at the top, "Glory to God in the highest, and on earth peace, good will toward men." The bell will not be rung until noon on the Fourth of July, when there will be 13 strokes, one for each of the original States. The largest bell ever cast in America was the alarm bell in the city hall in New York, weighing 23,000 pounds.

AVERILL CHEMICAL PAINT.—One of the proprietors of this journal rejoices in having used this paint over the entire outside of his humble mansion. He has also applied it inside of the same with equal satisfaction. We have no hesitation in saying we believe it to be not only a most exceedingly convenient, but excellent article as manufactured by the California Chemical Paint Co., No. 117 Pine street, S. F.

The Judges at the Centennial.

We print below a list of the judges who will award the premiums in the several departments of the exhibition. The method of awards adopted by the American Centennial Commission differs from the systems in use at other exhibitions. It dispenses with the international jury, and substitutes a body of judges, one-half foreign, chosen individually for their high qualifications. It dispenses also with the system of awards by graduated medals, and requires of the judges written reports on the inherent and comparative merits of each product thought worthy of an award, setting forth the properties and qualities, presenting the considerations forming the grounds of the award, and avouching each report by the signature of its author. The professional judgment and moral responsibility of the judges being thus involved, assures the integrity of their reports. To exhibitors such reports will be more valuable than medals. The list of the American judges is as follows:

GROUP I. Minerals, Mining and Metallurgy. A. L. Holley of New York, T. S. Hunt of Massachusetts, E. Harrison of St. Louis, S. J. Reeves of Pennsylvania, S. B. Axtell of New Mexico, J. W. Mackey of Nevada, Matthew Addy of Ohio, J. D. Hagne of California, W. S. Keyes of Nevada, Fred Prime, Jr.

GROUP II. Pottery, Glass, Artificial Stone, etc.—Gen. Q. A. Gilmore, U. S. A., Arthur Beckwith of New York, E. T. Cox of Indiana, Hector Tyndale of Pennsylvania, O. M. Chaffiet of South Caroliua.

GROUP III. Chemistry and Pharmacy, including the Apparatus.—C. A. Joy of New York, F. A. Genth of Pennsylvania, J. Lawrence Smith of Kentucky, C. F. Chandler of Pennaylvania.

GROUP IV. Animal and Vegetable Products, and the Machinery for their Preparation.—E. N. Horsford of Massachusetts, L. B. Arnold of New York, Col J. F. Tobias of Pennsylvania, Col. John Bradford of Florida, Geu H. M. Naglee of California, Geirdo Marks of Ohio, Ryland T. Brown of Indiana, Walter J. Green of Wisconsin, Deoatur H. Miller, of Maryland, James M. Shaffer of Iowa.

GROUP V. Fish and Fish Products, Apparatus of Fishing, etc.—Seth Green of New York, S. F. Baird of Washington.

GROUP VI. Timber, Worked Lumber, Parts of Buildings, Forestry —Wm. H. Brewer of Connecticut, J. M. Bennet of West Virginia, Prof. J. S. Newberry of New York.

GROUP VII. Furniture, Upholstery, Woodenware, Baskets, etc.—Addison Boyden of Massachusetts, Chauncey Wiltse of Nebraska, Gen. Gibbon of Montana.

GROUP VIII. Cotton, Linen and other Fabrics, including the Materials and Machinery.—Ed. Atkinson of Boston, Hugh Wardell of Savannah, Ga.; Col. Ed. Richardson of Jackson, Miss.; Samuel Wahler of New Hampshire, A. D. Lockwood of Rhode Island, Charles H. Wolfe of Ohio, George O. Baker of Alabama.

GROUP IX. Wool and Silk Fabrics, including Materials and Machinery.—John L. Hayes of Massachnsetts, E. C. Cowdin of New York, ——Bontillier and C. J. Ellis of Pennsylvania, J. Lang of Maine, Barton H Jenks of Pennsylvania, H. C. Goodspeed of Utah, Judge Williams of Iowa.

GROUP X. Clothing, Furs, India Rubber Goods, Ornaments and Fancy Articles.—W. H. Chandler of Pennsylvania, Benjamin Britton of New York, W. A. Linthicum of New York, Prof. W. C. Kerr of North Carolina, Dr. George W. Houston of Colorado.

GROUP XI. Jewelry, Watches, Silverware, Bronzes, etc. M. L Kennard, Peter Gottlesben of California.

GROUP XII. Leather and Manufactnres of Leather.—Ex-Gov. F. H. Pierpont of West Virginia, John Cummins of Massachusetts, Thomas Miles of Pennsylvania, W. B. Haselton of St. Louis.

GROUP XIII. Paper Industry, Stationery, Printing and Book Binding.—James M. Wilcox of Pennsylvania, Charles O. Chapin of Massachnsetts, William Faxon of Connecticnt, W. W. Oouly of Ohio, H. F. Brion of Maryland.

GROUP XIV. Apparatus of Heating, Lighting, Ventilation, Water Supplies and Drainage.—O. O. Cox of Washington, Dr. Azel Ames of Massachusetts.

GROUP XV. Builders' Hardware, Edge Tools, Cutlery, etc.—Daniel Steinmetz of Pennsylvania, Charles Staples of Maine, George L. Bead of Pennsylvania, Gen. Imboden of Virginia.

GROUP XVI. Military and Sporting Arms, Weapons, Apparatus of Hunting, Explosives, etc.—S. O. Lyfort, U. S. A.; H. Abbott, U. S. A.; George A. Hamilton of Minnesota.

GROUP XVII. Carriages, Vehicles, and Accessories.—Thomas Goddard of Boston, B. F. More of Maine, B. C. Shaw of Indiana.

GROUP XVIII. Railway Plans, Rolling Stock and Apparatns, Road Engines, etc.—R. E. Ricker of New Jersey, Gen. Morris of Indiana, Pelican Statalafer of Pennsylvania.

GROUP XIX. Vessels and apparatns of transportation.—Isaac Newton of New York, J. W. Griffiths of New Hampshire.

GROUP XX. Motors, Hydraulic and Pnenmatic Apparatus, etc.—Charles F. Porter of New Jersey, Joseph Belknap of New York, J. F. Holloway of Ohio, James Moore of Pennsylvania, Horatio Allen of New Jersey.

GROUP XXI. Machine Tools, Wood, Metal and Stone.—Irving M. Scott of California, G. H. Blelock of Massachusetts, W. F. Durfee of Wisconsin, J. A. Anderson of Kentucky.

GROUP XXII. Machines, Apparatus and Implements Used in Sewing and Making Clothing, Lace, Ornamental Objects, Pins, etc. —George W. Gregory of Massachusetts, E. H. Knight of Washington, L. D. T. Poor of Dakota.

GROUP XXIII. Agricultural Implements, and Implements of Horticnlture and Gardening.—John P. Reynolds of Illinois S. L. Grinnell of Washington. George E. Waring of Rhode Island, James Bince of Oregon.

GROUP XXIV. Instruments and Apparatus of Hygiene, Medicine, Surgery, Prosthesis, etc.—Dr. C. B. White of New Orleans, J. Henry Thompson of Washington.

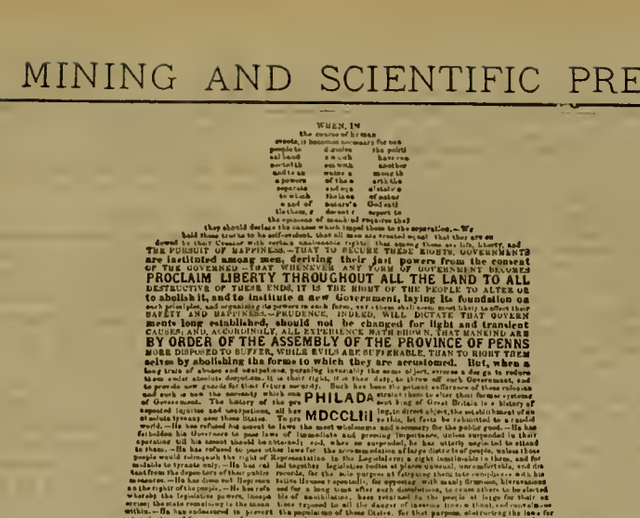
GROUP XXV. Instruments of Precision, Research, Experiment and Illustration, including Telegraphy and Music.—Prof. F. A. P. Barnard of New York, J. E. Hilgard of U. S. Coast Survey, H. K. Oliver of Massachusetts, George F. Bristow of New York, Prof. Watson of Michigan.

GROUP XXVI. Architecture and Engineering.—James B. Eads of St. Louis, Gen. W. B. Franklin of Connecticnt, Richard M. Hunt of Rhode Island.

GROUP XXVII. Plastic and Graphic Art, Sculptnre.—C. C. Perkins of Boston, J. Taylor Johnston of New York, James L. Cleghorn of Philadelphia, Brantz Mayer of Maryland, D. G Mitchel of Connecticut, G. W. Nichols of Ohio, J. W. Draper, Jr., of New York.

GROUP XXVIII. Education and Science.—Andrew D. White of New York, Daniel C. Gilman of Maryland, J. M. Gregory of Illinois, J. W. Hoyt of Wisconsin.

Among the English judges are Sir John Hawkshaw, John Coleman, Prof. Olling, Dr. Forbes Watson and Sir Charles Reed, M. P.; and among the French judges is the Marquis de Rochambeau, grandson of the count of Revolutionary fame. The judges from other foreign countries are not yet elected, or at least the lists have not yet been sent in. There are to be 125 American judges in all, and 100 foreign judges. Foreigners will be paid $1,000 for their services, and the Americans $600.



WHEN, IN
the course of human
events, it becomes necessary for one
people to
dissolve
the political
bands
which have con
nected them
with
another
and to as
sume among
the powers
of the
earth, the
separate
and equal
station
to which
the laws
of nature
and nature's
God entitle
them,
a decent
respect to
the opinions of mankind requires that
they should declare the causes which impel them to the separation.—We
hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain inalienable rights, that among these are life, liberty, and
THE PURSUIT OF HAPPINESS.—THAT TO SECURE THESE RIGHTS, GOVERNMENTS
are instituted among men, deriving their just powers from the consent
OF THE GOVERNED.—THAT WHENEVER ANY FORM OF GOVERNMENT BECOMES
PROCLAIM LIBERTY THROUGHOUT ALL THE LAND TO ALL
DESTRUCTIVE OF THESE ENDS, IT IS THE RIGHT OF THE PEOPLE TO ALTER OR
to abolish it, and to institute a new Government, laying its foundation on
such principles, and organizing its powers in such form, as to them shall seem most likely to effect their
SAFETY AND HAPPINESS.—PRUDENCE, INDEED, WILL DICTATE THAT GOVERN
ments long established, should not be changed for light and transient
CAUSES; AND, ACCORDINGLY, ALL EXPERIENCE HATH SHOWN, THAT MANKIND ARE
BY ORDER OF THE ASSEMBLY OF THE PROVINCE OF PENNS
MORE DISPOSED TO SUFFER, WHILE EVILS ARE SUFFERABLE, THAN TO RIGHT THEM
selves by abolishing the forms to which they are accustomed. But, when a
long train of abuses and usurpations, pursuing invariably the same object, evinces a design to reduce
them under absolute despotism, it is their right, it is their duty, to throw off such Government, and
to provide new guards for their future security. Such have been the patient sufferance of these colonies
and such is now the necessity which con
PHILADA
strains them to alter their former systems
of Government. The history of the pre
MDCCLIII
sent King of Great Britain is a history of
repeated injuries and usurpations, all having
in direct object the establishment of an
absolute tyranny over these States. To prove this, let facts be submitted to a candid
world.—He has refused his assent to laws the most wholesome and necessary for the public good.—He has
forbidden his Governors to pass laws of immediate and pressing importance, unless suspended in their
operation till his assent should be obtained; and, when so suspended, he has utterly neglected to attend
to them.—He has refused to pass other laws for the accommodation of large districts of people, unless those
people would relinquish the right of Representation in the Legislature, a right inestimable to them, and for
midable to tyrants only.—He has called together legislative bodies at places unusual, uncomfortable, and dis
tant from the depository of their public records, for the sole purpose of fatiguing them into compliance with his
measures.—He has dissolved Representative Houses repeatedly, for opposing with manly firmness his invasions
on the rights of the people.—He has refused for a long time after such dissolutions, to cause others to be elected,
whereby the legislative powers, incapable of annihilation, have returned to the people at large for their ex
ercise; the state remaining in the mean time exposed to all the danger of invasion from without, and convulsions
within.—He has endeavored to prevent the population of these States; for that purpose obstructing the laws for
naturalization of foreigners, refusing to pass others to encourage their migrations hither, and raising the conditions
of new appropriations of lands.—He has obstructed the administration of justice, by refusing his assent to laws for estab
lishing judiciary powers.—He has made judges dependent on his will alone, for the tenure of their offices, and the
amount and payment of their salaries.—He has erected a multitude of new offices, and sent hither swarms of officers
to harass our people, and eat out their substance.—He has kept among us, in times of peace, standing armies, without
the consent of our Legislatures.—He has affected to render the military independent of, and superior to, the civil power.
He has combined, with others, to subject us to a jurisdiction foreign to our Constitution, and unacknowledged by our laws;
giving his assent to their Acts of pretended Legislation.—For quartering large bodies of armed troops among us.—For protect
ing them, by a mock trial, from punishment for any murders which they should commit on the inhabitants of these States.
For cutting off our trade with all parts of the world.—For imposing taxes on us without our consent.—For depriving us, in many
cases, of the benefits of trial by jury.—For transporting us beyond seas to be tried for pretended offenses.—For abolishing the free
system of English Laws in a neighboring Province, establishing therein an arbitrary Government, and enlarging its boundaries, so
as to render it at once an example and fit instrument for introducing the same absolute rule into these Colonies.—For taking away
our charters, abolishing our most valuable laws, and
altering, fundamentally, the powers of our Governments.—For suspending our
own Legislatures, and declaring themselves invested with power to legislate for us in all cases whatsoever.—He has abdicated Govern
ment here, by declaring us out of his protection, and waging war against us.—He has plundered our seas, ravaged our coasts, burnt our
towns, and destroyed the lives of our people.—He is at this
time, transporting large armies of foreign mercenaries to complete the works of
death, desolation and tyranny, already begun with circumstances of cruelty and perfidy scarcely paralleled in the most barbarous ages, and
totally unworthy the head of a civilized nation.—He has excited
treasonable insurrections of our fellow-citizens, with the aim of bringing on the inhabitants of our frontiers the merciless Indian savages, whose known rule of warfare is an undis
tinguished destruction of all ages, sexes and conditions.—In every
stage of these oppressions, we have petitioned for redress in the most humble terms; our
repeated petitions have been answered only by repeated injury.—A
prince whose character is thus marked by every act which may define a tyrant, is unfit
to be the ruler of a free people.—Nor have we been wanting in atten
tion to our British brethren.—We have warned them, from time to time, of attempts made
by their legislature to extend an unwarrantable jurisdiction over us.
We have reminded them of the circumstances of our emigration and settlement here.
We have appealed to their native justice and magna
nimity, and we have conjured them, by the ties of our common kin
dred, to disavow these usurpations, which would inevitably interrupt our
connections and correspondence.—They, too, have been deaf to the voice of justice and con
sanguinity.—We must, therefore, acquiesce in the necessity which denounces
our separation, and hold them, as we hold the rest of mankind, enemies in war, in peace
friends.—We, therefore, the Representatives of the United States of Ameri
ca, in General Congress assembled, appealing to the Supreme Judge of the World for the recti
TUDE OF OUR INTENTIONS, DO, IN THE NAME, AND BY THE A
UTHORITY OF THE GOOD PEOPLE OF THESE COLONIES, SOLEMNLY PUBLISH
and declare, that these United Colonies are, and of right
ought to be, Free and Independent States; that they are absolved from
all allegiance to the British Crown, and that all political connection between us
and the State of Great Britain, is, and ought to be, totally dissolved; and that, as Free and
Independent States, they have full power to levy war, conclude peace, contract
alliances, establish commerce, and to do all other Acts and things which Independent States
may of right
do. And
for the sup
port of this De
claration, with
a firm reliance
on the protection
of Divine Providence
e, we mutually ple
dge to each other
our lives, our
fortunes, a
nd our sa
cred honor

A RINGING DECLARATION.

Off for Philadelphia.—The Centennial base ball club of this city left here on Saturday for the East on a three months' tour. The players chosen to represent California are Messrs. Taylor, Gill, Keating, Curran, Williams, Parent, Thompson, Piercy and O'Brien, with Messrs. Cullen, Ashley and Walker as substitutes. The club has been presented with a magnificent gold badge, to be given to the player making the best record. On July 4th they will play at Omaha. The first game with professionals will be at Chicago with the noted White Stockings.

THE AMERICAN EAGLE.

Whan freedom, from her mountain hight,
Unfurled her banner to the air,
She tore the azure robe of night,
And set the stars of glory there!
She mingled with its gorgeous dyes
The milky baldric of the skies,
And striped its pure, celestial white
With streakings from the morning light.
Then, from his mansion in the sun,
She called her eagle bearer down,
And gave into his mighty hand
The symbol of her chosen land!

Majestic monarch of the cloud,
Who rear'st aloft thy regal form,
To hear the tempest-trumpings loud,
And see the lightning lances driven,
When strive the warriors of the storm,
And rolls the thunder drum of heaven,—
Child of the sun! to thee 'tis given
To guard the banner of the free,
To hover in the sulphur smoke,
To ward away the battle stroke,
And bid its blendings shine afar,
Like rainbows on the cloud of war,
The harbinger of victory.—*Jos. Rodman Drake.*

The following truly national poem should be revived with the Centennial Fourth:

"Keep your eye fixed on the American eagle,
Whom we as the proud bird of destiny hail;
For that wise fowl you never can inveigle
By depositing salt on his venerable tail."

A Good way to fasten screws that have become loose, is to fill up the holes tightly with cork. Screws and irons so secured will remain perfectly tight, as when put into new wood.

Who'll Till Our Fields a Hundred Years From Now?

BY HON. EBENEZER AYERS.

Who'll till our fields a hundred years from now?
Fields dear to us by many a lasting tie,
Fields our own hands redeemed from natnre's sway,
For which we fought to conquer or to die.

On the drear wild, by copse, by hill, by stream,
Our humble cabins hopefully we reared,
And with the partners of our earlier years,
Our trials, hopes and fears and joys were shared.

We drove the plowshare o'er wild nature's glebe,
And changed the wilderness of the native plain,
And in its stead there rose a boundless sea
Of growing, ripening, emerald waving grain.

Then here and there the village—city rose,
And deft mechanics came with ready skill;
The schoolhouse rises—then the church's spire,
And hy each gurgling brook, the busy mill:

And here and there, on some uncultivated knoll,
The marble tombstone rises o'er the head
Of many a pioneer—the loved and lost—
The founders of new cities of the dead.

Who'll be the joyous tillers of these fields,
And with true yeoman zeal will hold the plow,
And with the faith, and with the ardent hope,
That fills the bosoms of the owners now?

No, not such faith, and not such sanny hope,
As filled the bosoms of the pioneers—
For hazard, douht, and perseverance joined,
The noble prize achieved much more endears.

Who'll fill the churches on that Sabbath morn,
And join their voices in the hymn of praise?
Who'll fill the halls of legislation then?
Who win the civic or the material bays?

Who'll be the jolly Grangers of that day,
And spread the banquet in the festive halls;
Fill every station in the walks of life,
To which their pleasure or their duty calls?

Perhaps some antiquated man may say,
To the forthcoming centenary race,
He knew a few gray headed, tottering men,
That were the pioneers of such a place.

That long, long since those early pioneers
Had sunk beneath the sod their plowshares turned,
And naught remains except the lands they tilled,
And some posthumous lame for good deeds earned.

Impatient nature heads no laggard wish,
But ever crowds succeeding seasons on,
And, will we, nill we, hurls events along,
Till days and years and centuries are gone.

Childhood will patter, joyous youth will laugh,
Fashion still rule with undisputed sway,
Ambition fire the aspiring statesman's heart,
And equal vanity affect the gay.

The limpid lakes that gem this prairie land
Will gleam as brightly in that future hour
As when the pioneers first stood, amazed,
Then reared their cabins by their pebbly shore.

The genial sunshine and refreshing shower,
Still bless the honest hand that holds the plow;
But all unknown to us the coming men,
Who'll till our fields a hundred years from now.

The Root-Cap of a Plant.—A recent writer remarks: "The idea held by the earlier botanists, that the tips of all roots consisted of spongy masses of tissue, by means of which plants were enabled to soak up their food from the soil, has, with the aid of the microscope, been entirely discarded. The term spongiole, which was given to these theoretical bodies, is a landmark of departed ignorance, and furnishes a striking contrast with the known structure (the root cap), with which the tip of every growing root is covered. With the leading botanists of to-day a root is considered to be an outgrowth protected by a cap. This definition seems very short, but if anything further is added, there comes with it a number of exceptions. The name which this covering to the root-tip has received is in itself very descriptive, as it is truly a cap, consisting of a number of layers of quite dense cells surrounding the extremity. These root-caps vary in size in different species of plants; sometimes they are so small that only with the high powers of the microscope can they be seen, while on the other hand they may be readily observed with the naked eye."

Adulteration of Sugar.—A case of adulteration of sugar, recently tried at Marseilles, has excited a good deal of attention there. Fraud of the kind had long been suspected by the customs officials, and the cargo of sugar in the present case was from Reunion. The Reunion sugars of brown hue are very rich in saccharine matter, and well suited for mixture. It was first thought that the sugar had been mixed with pounded bricks and sand, but on analysis the added matter was found to be slag (a sort of opaque glass formed in the working of various metals, or vitreous lava from volcanoes) along with sand, and an economy of 12 fr. per 100 kilgos. was anticipated. The slag has a bright granular fracture, so that it makes a very good imitation of sugar. The sand was added to make up the weight.

Fine Proof Suit.—An extraordinary fireproof suit, invented by a Swede named Oestberg, was recently exhibited in Vienna, in the presence of the Emperor William and several other distingnished personages. One Captain Ahlstrum, clothed in the suit, walked into an immense fire, prepared for the occasion, of wood saturated with petroleum. The account says: "The heat of the fire was so intense that no one else could approach within eighty paces without being burnt or scorched, but the Captain walked around in the glowing pile perfectly undisturbed, leaning on the burning wood, and finally seated himself on the coals." After remaining in the fire a quarter of an hour, the salamander came out perfectly unharmed, and without "the smell of fire upon his garments."

The Fourth of July in San Francisco.

Arraugsments are complsted to make the observation of ths Fourth of July in this city one of the most notable and interssting ever planned. Land aud water, sea and shore will furnish the double field for the exercisss of cslebration. On Monday, July 3d, npon land, thsre will he the sham battle and the brilliant display of msn at arms, and on the watera of the hsrbor there will be hombardment hy forts and ships of war. Solid shot and murderons shsll will hslch forth from forts and port-holes. In all fsaturss, savs that the marks to bs firsd at ars a harren rock and a craft without a crew, the engagement will hs as real as heavy shot and dry powder can make it.

Our illustration shows the field of conflict. In the foregrennd is the Presidio Reservation, where the sham battle of ths morning of July 3d will take place. On the water the scene, which those acqnainted with the bay will recognize aa lying at the entrance to our harbor, embfaces a stretch four milea in diameter, and across this the ahot and shell will he hurled. The general outline of arrangementa is as follows:

The Attack on Sea and Land

Will ue made in three positious. The dotted lines in the engraving represent the shot fired from the forts and fleet at the first position.

The linea formed hy a dot and dash represent the second position.

The solid unbroken lines represent the third position.

A Represents Fort Point.
B. Lime point.
C. Fleet of war vessels in first position.
D. Angel island.
E. Alcatraz island.
F. Visiting frigatea.
G. Black point (Point San Jose).
H. Fleet of war vessels in second positiun.
I. Harbor View.
J. California Guard Battery of Second Brigade.
K. First, Second and Third Regiments Infantry, with nnattached companies, forming the infantry portion of the Second Brigade.
L. Major Hashrouck's Battery, Fonrth Artillsry, U. S. A.
M. Major O'Brien's Cavalry of Second Brigade.
N. Presidio garrison.
O. Fire ship, to he destroyed by batteries.

The firing in the first position (dotted lines) will he directed to Lime point, and will be sustained from the fleet, from Fort Point, from Major Haatronck's battery, and the California Guard Battery, from Alcatraz, and from Black point. While sufficient racket will he created in thia movement to typify a hombardment, the resnlt attained will he little more than target practice from differeut angles aud distancea with flying shots from the fleet.

In the aecond position (dots and dashes) the fire ship will he brought into prominence and will he treated as a hostile iron-clad, or, in accordance with the imagination of the on-lookers, aa a whole fleet of monitors helonging to an imaginary euemy. The lines in the diagram represented hy a dot and dash indicate the direction of the firing at the ship. The fleet will circle round while firing, as in the Port Royal tactics.

In the third poaition (straight lines) an exhibition will he given of long-distance firing with shell from Fort Alcatraz.

The Military Display

Will precede the naval maneuvres and the cannonading, and will hegin about 10: 30 A. M.

In an order issued from the Headquarters of the Second Brigade, the commanders of the infantry regiments and captains of unattached companies will report to the Assistant Adjutant-General, on the Presidio Reservation, on the 3d instant, at 9 A M., promptly, taking the cars of the Central railroad company to Post street and Cemetery avenue, thence along Cemetery avenue to the Presidio Reserve by the new road prepared for the troops.

Major H. R. O'Brien, commnnding the Cavalry Battalion, will report with two companies of his command to Adjutant General Walsh, at the Cosmopolitan hotel, at nine o'clock, for eacort duty.

The Commander of the Light Battery, Company A, California Guard, nnattached, will report his command to the Assiatant Adjutant-General at nine A. M., Presidio Rsserve.

The whole of the Presidio Reserve east of the garrison is deaignated as the review ground, which the Field Officer of the Day will protect. Major Jamea A. Lavan, Second Regiment, N. G. C., ia detailed as Field Officer of the Day.

At ths Presidio.

A salute of seventeen guns will be fired on the arrival of the Governor and etaff at the Presidio. The formal review ceremouiea will then he proceeded with and after an interval for lunch the taotial evolutions will be executed. Twenty rounds of hlank ammunition will be issued to each man on the field. The column of hattalions will be deployed into line. The liue will wheel by fours to the left, and next form a new liue of battle by moving forward to the left of the firat four hy a left obliqne movement. As qnick aa the variona subdiviaions arrive in the line they will wheel about by fours, thns bringing the new line of battle faced to the rear—that is, faced iu the opposite direction to which the column of fours were approaching at the moment the movement was ordered. A vsry picturesque evolution will follow. The battalions will form double columns of fonrs and move to the new front in this formation. After gaining the necessary ground to ths front, ths hattalions will again dsploy forward into line of hattle and facs ahout. An advance by echelon from the right will bs nsxt presented for the admiring gaze of the mnltitnde. Looking down upon the troops they will appsar to ths eye like the hlack squares on a checkerhoard seen diagonally. After the necessary interval of rsst, the battalions will describe a half wheel to the lsft into line of hattle, thus giving an obliqne change of front. The imsginary enemy is presnmed to be in this front, and skirmishers will he sent forward to ascsrtain his intention. They discover him in force and the ssngninary work commences. General McComh, to prsvent his army from bsing utterly annihilated hy the stubhorn rssistance of the foe, will attack it in two lines, the linss advancing, altsrnately passing through each other, and pouring hy turns a shower of paper wads on the enemy, who is now offering auch obstinate resistance that the skirmishers are called off and a mnrderoua fire hy hattalions is directed upon his lines. Under this fisrce onslaught he wavers and reels hack, leaving his wonnded on the field. Like all great captains, the commanding general takes advantage of the enemy's display of weakness, and orders a magnificent advance in line, which culminatea in a heroic hayonet charge. The remnanta of the enemy haviug heen diapersed or captnred, a halt is called, the deadly fire is stopped and the broken lines readjusted. Theu the victoriova army will be dismissed with a benediction, and the soldiers will retire to their homes and once more don the nnpretending garh of the civilian. Spectators who desire to witnesa the glittering pageant will find favorable pointa of observa tion on the surrounding hills. The position from which the plan of operationa is supposed to he taken will he the most desirahle vantage ground. The beat ronte for visitors will he along Cemetery avenue, taking the California or Bush street cars. This will hring them straight to the R aervation, when they can readily take to the hills and select the point of view that suits them best.

The naval display is not likely to last over an hour, and it is expected that all the manenvers will be completed by 3 P M.

On the Fourth

There will he arranged one of the grandest parades and atreet displays ever witnessed on the coast. Already flaga are festooning Kearny street from end to end. In the paraed on the Fourth, civic and military organizationa will join. The line of march will he aa follows: From Second to Montgomery, to Montgomery avenue, to Kearny, to Market, to Ninth, to New Montgomery, to Mission, to the pavilion. At the pavilion there will be stirring and patriotic apeeces. Rev. Dr. Stebbins is the orator of the oay. Addreases are expected from the Governor and distinguished citizens. In the evening the city will be a hlaze of light aud life and resonant with music. Those of our country friends who choose to pass the holidays in the city may be aure of a varied and enlivening entertainment.

An Early Celebration.

A portion of the aigners of the Declaration met two years after, for a cheery commemoration of their great achievement, in the Philadelphia City tavern. The enjoyment of the occasion was enhauced by the recent deliverance of the city from the presence of General Howe, and hy the contrast hetween this featival and that lately given hy the British officers to him. A brief glimpae at the patriotic occasion, from the hitherto nnpuhlished diaries of William Ellery, may well close this narrative.

"On the glorious Fourth of July [1778], I celebrated in the City tavern, with my brother delegates of Congresa and a number of other gentlemen, amonnting, in the whole, to about eighty, the anuiversary of Indepeudency. The entertainment was elegant and well conducted. There were four tables spread; two of them extended the whole length of the room, the other two crossed them at right angles. At the end of the room, opposite the npper table, waa erected au orchestra. At the head of the upper table, and at the President's right hand, stood a large haked pndding, in the center of which was planted a staff, on which was displayed a crimson flag, in the midst of which was this emblematic device: An eye, denoting Providence; a label, on which was inscrihed, 'An appeal to Heaven;' a man with a drawn aword in his hand, and in the other the Declaration of Indepeudency, and at his feet a scroll inscrihed, 'The declaratory acts.' As aoon as the dinner hegan, the music, consisting of clarionets, hantboys, French horns, violins and bass viols, opened and continued, making proper pauses, until it was finished. Then the toasts, followed by a discharge of field-pieces, were drank, and so the afternoon ended. In the evening there was a cold collation and a brilliant exhibition of fireworks. The street was crowded with people during the exhibition." —*Scribner's.*

A Letter from Spring creek, in the Black hills country, gives the following as the price of provisions there: Flour brings $16 per 100 pounds; bacon 35 cents psr pound; beans, 16 cents; corn meal, 14 cents; beefsteak, 20 cents; and everything else high in proportion.

At the Centennial.

Notes of Travel. Sight Seeing and Relic Hunting.

[For the Press.]

It is easy to imagine your sanctum overrun with Centennial notes, and were it not like rosemary, "just for remembrance," this would not he written at the risk of adding to the contents of your waste baskst. An imperativs telegram, snmmoning me to the opening of the Centennial exposition, gavs one day for preparation sud seven for the trip from Sacramento to Washington. Selecting the shortest gsographical route, *via* the "Omaha and St. Louis cnt off"—a new road inaugurated last Fsbruary, I missed the opening by 48 hours, on acconnt of wash-outs on said road in Nebraska, and have the consolation of helieviug that Providence thns interposed to spare me the crush and fatigne and mud of that notable day.

At the Exposition.

A week of sight seeing in and aronnd Washington was all the rest allowed me, preparatory to the first instsllment of thia greateat and grandest expoaition that the world ever saw.

The second week after the openiug found ns on the Centennial grouuds, housed in a "temperance hotel" five minntes' walk from the entrance on Elm avenue, near the main building. To encourage those who may he deterred from coming to Philadelphia through fear of high pricea of living, I will say that comfortahle rooms, accommodating two persons, may be had for $1 00 and $1.50 per day, and meals at 50 cents each aud upwards, either at hotels or restaurants, hoth outside and within the grounds. If one ia there merely to see the exposition, it is hy all means better to locate as near the center of attraction aa possible, and thus avoid the long and tedious trips to and from the city in crowded cars, at the expense of two or three hours daily. I would say to all those who intend coming, plan to stay as long as possihle, hut in any event come, if for ever so short a time. It may not happen again on our continent for many years, nor on any other, perhaps, that 40 different natione will he represented in a characteristic manner in one building, or that the finest collection of art ever exhibited in one place is grouped together ao that in less than a day's time it may at least he all glanced at, while the varions huildings that furnish headquarters for the commissioners of different nations are all highly characteristic and afford an opportunity of atudy and observation that only months of foreign travel can give.

The grounds are themselves delightful, and in Lansdowne valley one may enjoy a seat in the shade, hathe their hands in the romantic little stream that wanders through it, and at the same time listen to the wonderful strains from Gilmore's hand, that every forsnoon vies with the birds and hum of human voicss in that lovely rstreat.

If one can afford to take the Centennial lsisurely, it is a grsat rslief to vary ths inspection of exhibits in the the intsrior of the building hy strolling out among the fountains and lakes, among the quaint strnctnrss erected for many purposes, whsrs ons may almoat always find a seat and, if desirsd, a communicative companion, in the person of guard or exhibitor.

Our time hsing limited, we made the entire round of the exposition in three days, and, aftsr a rest, hegan the business of looking after specialtiss and nsw exhibits, which, I am vexed to say, will be opensd daily long after we reach ths Pacific coast, as now appears from the piles of nnpacked hoxes in the Turkish, Russian and Chinese departmsnts especially, and notably also in the department of art.

Securing Mementos.

There is still euough to see, and happy the mau or woman who does sse and appreciate it all. And I venture to say that no womau of culture will examine the rare laces and china, the exqnisite carvings in silver, wood and ivory, the hronzes, jewelry and embroideries, the pictures, statuary, tapestry and mosaica, without breaking the tenth commandment, or aomething near it, hy desperately wiahing for often impossible duplicates.

But one is met at every turn by the exasperating aasurance that nothiug can he removed from the Exposition until next November, and one day'a experience fully convinced us that the commiasioners are in earuest about this very proper restriction. Searching one morning for mementoa, we visited an npholstery section in the British department of the main huilding, where the week before the gentleman in charge had offered to sell a fine piece of satin damask, naed as a sample in taking orders for covering furniture. But meanwhile the Custom Houae officers had measured his goods, and threatened to shut up hia place and confiscate all it contained if at any time they were found not to exactly correspond with their inventory.

"But," said the exhibitor, "at Vienna we were allowed to hny and sell as much aa we chose, and turned the exposition into a regular hazaar." He ia allowed to take orders and deliver them as soon aa they can arrive from England, and New York people have already ordered aome of the choicest goods, that would grace a Sultan's palace.

But that was too far fetched for us, so we went over to a stout old Englishman in charge of a case of common English pottery in odd shapes and colors, the like of which he assured us in a tantalizing way were not to he fonnd in America. Would he sell that lovely green and brown teapot and creamer in rustic pattern? Yes, and it was very cheap, too, hnt we could not take it away. "You call this a free country," but he had never been so hampered and restricted in all his life. Some of the casea had been locked up and were under the seal of the Custom House inspectors, for selling and delivering a few trifles. So we parted with mutual regret, hut after all the grumhling of exhibitors and visitors, none of us would l ke to see this

Sham Battle and Grand Naval Bom

superb exposition spoiled by the confusion and continual change that must arise if what is on exhibition to-day were sold and removed to-morrow. However, there have been and are to be bazaars opened upon the grounds in connection with the Turkish, Italian and other department, where goods are to be sold and immediately delivered.

For ourselves, we were obliged to content us with the "flags of all nations," bookmarks and badges woven in machinery hall and the woman's building, Centennial fans, photographic views of the buildings, etc. But many homes will be enriched by these works of industry and art, as many are already marked "sold," and usually the name of the purchaser attached. We notice that newspaper writers complain that the

Prices of Goods

Are so constantly flaunted before the public, but I am sure the eager public are more than ready to forgive a weakness that furnishes knowledge they are so anxious to possess. This is not true of the marbles, however, as we saw no price affixed in any case, although many were labeled "for sale," or "sold." Indeed, many of them are so recently unpacked that they are not even catalogued, and no clue is furnished us to the origin or destiny of these exquisite gems of art. One little fellow in marble attracts great notice by the forlorn curl of his lip and two big tears rolling down either cheek because forced to say his prayers, the cross hung from his neck, and the label hinting that they are not of the sort that his tired little heart can appreciate. Another very beautiful and lifelike statue is a girl holding a plump, lusty looking baby, and at the same time a cup containing his food. She has taken a spoonful, and is cooling it by blowing, with the under lip curved with the exact touch of nature, while baby gives a lusty kick to show his impatience. This reminds me that I learned last night of several acts of vandalism in chipping bits from these marbles and even pictures as relics. We cannot see how sufficient protection is to be furnished in the way of barriers and official guards to keep such wickedly selfish beings from ruining some of the choicest works of art in existence, unless a public example can be made that will once for all intimidate every one subject to this temptation.

While in the art gallery I may as well speak of a

Mosaic Picture of Washington

Which hangs in memorial hall, on the left as you pass out to the annex, which has been "presented to the city of Philadelphia as a souvenir of independence declared in that city July 4th, 1776. Presented by L. A. Gallandt, mosaic manufacturer, Rome." The work is finely executed and of life size, but the color is just the tinge of yellow that one sees in subjects of fever and ague along the Missouri river; and of course it is unmistakably Washington, but one grows so tired of his tame physiognomy as seen on paper weights, glass statuettes, book marks, etc, that one needs to be exempt from the sight of all of them for a while before judging without prejudice any likeness of the Father of our Country.

Mosaics.

In the first room of the annex are displayed the wonderful Florentine and Roman mosaics, hung in pictures on the walls and disposed about the room as slabs for the tops of tables or already mounted.

One of the finest, inlaid in ebony, represents a harp and statuary, vase and flowers and artists' tools; price $5,000. Next to this is one still more elaborate, also in ebony, a scroll of music (Norma), masque, guitar, book in pearl, Comedy of Dante, vase of flowers, painter's palette and globe in a frame; $10,000. Another, but not so beautiful, is a Florentine mosaic inlaid in real porphyry; $5 000.

One of the most beautiful was an ebony slab, inlaid with grass, flowers, shells, and a full length figure of Flora, a locket, with ribbon of malachite, exquisitely inlaid with lilies of the valley and forget-me-nots; $5,000, gold. And so on down to $3,000, even which seems rather a high figure for republican America in these hard times. I didn't mean to take you to the art gallery, it is such a bewildering, hopeless sort of a place, and withal so fascinating that once inside only the order of the guards to close would release you from the spell.

The State Buildings.

The hour for closing all the buildings is six o'clock, but one evening a lady companion and myself presumed upon the courtesy of the officials and made a tour of the, State buildings, which are situated in the most delightful part of the grounds, nearly all in a line and facing the beautiful lake and main buildings, bridges and lawns. Sitting on the porches in the rear and looking down the beautiful lawns, shaded by trees of natural growth, one could easily imagine himself at home, whether in New Hampshire, New Jersey or wherever that favored spot might chance to be.

The gentlemen in charge were in several cases sitting upon the front porch with a look of supreme affability and content, and to our remark that "it was rather late to call," gracionsly responded that "the latch string was always out and they were very glad to see us." A book for registering names of visitors is kept in each of these buildings, although some are exclusively for residents of the State owning the building, and one cannot help remarking that the line of free hearted cordiality decidedly tends towards the West, in this as in most other matters.

All styles of architecture are represented, from the little log cabin of Mississippi on the hill, hung with gray moss, to the stately stone building of Ohio and the foreign looking house of many rambling roofs, covered with red tiles, claimed by New Jersey, and, I had nearly forgotten to say, the California building with its swell back and dome-like appendage on top, which gave rise to all sorts of speculations as to whether it was a huge water tank or Mohammedan mosque. However, we are assured that it will be a very fine hall when finished, and it is rapidly approaching completion.

Searching for specialties one day, we visited the

Colorado and Kansas

Building, which was not yet open to visitors, but we quietly ignored the sign "no admittance" and went around to a side door, where the Kansas commissioner kindly received us, introduced us to the exhibits, which are among the finest of the kind on the grounds and the most tastefully arranged, unlocked the ladies' parlor, gave us seats and went to find Mrs. Maxwell, the Colorado huntress who has killed over four hundred wild beasts and stuffed them, together with a large collection of birds, which are to be exhibited in the Colorado section of this joint building.

Many of the animals were already mounted upon the artificial rocks and mountains which she was helping to construct in one corner of the main hall. Her manner was cordial and womanly to the last degree, and she chatted modestly of her exploits in killing buffalo, elk, foxes, wolves, bears, eagles, etc., saying that her husband was not always at hand when she needed to use a rifle, so she had learned to use one herself.

Another notable we were anxious to interview was the lady engineer who runs the Baxter engine that operates the looms in the woman's building. We found her in the little brick annex in the rear, dressed in an embroidered linen suit, looking as clean and cool as if in a parlor. She had always been familiar with engines in her father's mills in Canada, had studied the subject with her brother, who is a civil engineer, and perfected her knowledge by a thorough course elsewhere. She pretorred the business to teaching school, and there were several young ladies expecting to take lessons of her this summer.

Specialties.

Supposing that everybody knows what is in the woman's building, I will only say that I noticed a large display of Mrs. Flynt's reform garments, and heartily regretted that Mrs. Curtis, of San Francisco, Cal., could not have matched her own inimitable inventions beside these and thus given the world another valuable hint towards reform in the right direction.

Another special exhibit was 90 varieties of apples, received from Melbourne, Australia, last week, *via* San Francisco, all in fine condition, displayed in Victorian court, main building. Each variety was carefully labeled, and some of them looked very fine. All were ripened in March, the exhibitor said, but he looked so unmistakably "hands off," that we didn't ask to be allowed the privilege of eating a foreign apple, as we were tempted to do.

The exhibit of fruits from Jamaica in agricultural hall, to be followed by others during the season, attracted much attention. Shaddock, mangoes, yams, mammee apples, jack-fruit, convey but little meaning to the untraveled native American mind, but it was some satisfaction to us to put our index finger into some of it, through the coarse netting thrown over it, to ascertain its degree of softness and to express our dissatisfaction that it was all to rot and be thrown away in a few days, when we wanted to put a tooth into some of it so very much. The sapodillos are about twice the length of an apricot, with about the same width, thickness, color and texture of skin.

The exhibitor indulged my vindictive punch into one of them, and seemed to make due allowance for my feminine curiosity to taste the forbidden fruit.

The mammee apples are an extremely rough looking, russet fruit, about the size and shape of an ordinary apple.

The exhibits on this table are to rotate during the season, it being filled the week previous with tempting Michigan apples, which were distributed about somewhat promiscuously.

Near this section is "Old Abe," the veteran Wisconsin war eagle, the hero of 25 battles, who exhibits his soldierly bearing daily for the benefit of the ornithological society in the State that is so justly proud of his career and history. His life and photograph are for sale by the soldier who carried him as the battle flag of the Eighth Wisconsin during the late war.

One afternoon we reveled among sewing machines, and discovered two which make a lock stitch without a shuttle, the Wardwell and Monitor, a consummation for which so many have been anxiously waiting these long years. They are just being introduced into market and seem to possess all the excellencies of other first-class machines.

Darning Machine.

Being mindful of the injunction of the stocking-darner of our family, to purchase a machine for performing that labor, I was glad to stumble accidentally upon one in machinery hall, and enjoyed seeing a gentleman darn a hole, made for the purpose of showing off this "cast iron grandmother," in the most improved manner, which he graciously bestowed upon your correspondent, while a lady remarked it would be handy to have one's husband do up the family darning in the evening, while the wife read the papers.

C. A. Colby.

Washington, D. C., June 8th, 1876.

The Celebration in New York.—A telegram from New York says: Preparations for the celebration of the third and fourth are almost completed. The parade will be one of the most imposing demonstrations ever witnessed in this city. The entire first division of the National Guard will turn out and a number of civic societies are to participate. It is calculated the procession will be five miles long. The processionists will carry torches. The houses on the route are to be brilliantly illuminated.

A Centennial Tribute.

[Composed by Sarah Morton, of Merced, graduate of the College of Notre Dame, of the class of 1876.]

Tho' many a poet's hands have swept
With wondrous touch the mystic lyre,
And strains of patient sweetness stirred
Our hearts with their impassioned fire,—

Tho' thousands still in silvery tones
Will consecrate this hallowed theme,
Yet would a daughter of the West
Fain cast one leaflet in the stream.

One leaflet from Pacific's shore,
From California's lovely State,
Upon the mighty onward tide
That flows through Freedom's golden gate.

One leaflet 'mid the wealth of flowers
Strewn round our fair land's deathless fame
By pens inspired with magic power
Her peerless prowess to proclaim.

One bud among the votive wreaths
That grace Centennial gold-draped halls,
A tribute of the glorious past
Ere down the silvery curtain falls.

And softly borne on pinions glad,
Like crystal spray beneath the sun,
Are echoed far from shore to shore
The deeds our noble sires have done.

Theirs is the glory, ours the weal,
And as our suns in splendor glow,
We reap the golden seed they sowed
Just one bright hundred years ago.

Oh, ever bright be their pure bays,
And green the mounds of fallen brave;
In blood they wrote their glowing tale,
They fell our own dear land to save,

Then when liberty's sun was set
And freedom crushed and panting fell,
Till Britain's swords ceased clashing, and
Her guns grew cold in Yorktown's dell—

A hundred years ago! What thoughts
Rise up like stars in night's dark dome,
Of those who nobly lived and died
To win us freedom's happy home.

Atlantic's stormy billows heaved
A hundred years ago as now,
But what a change those years have wrought
Upon our country's noble brow.

The East, then but in part unveiled,
Has since the curtain folds unrolled,
And where the wild untrodden glade
Once stretched, now dome and spire behold.

And in the far-off, boundless West,
'Mid unmarred splendor rich and rare,
Vast rolling plains and forest bowers
Unknown were spread in grandeur there.

Her giant pines with æolian strains,
Till o'er the grand old forest dells
And streamlets spanned by Iris dyes
All softly sweet the cadence swells.

Broad fields of waving grain now bend
Where once were barren, wildwood plains,
And mighty falls and rivers swell
Successful labor's choral strains.

And o'er the land from East to West,
The iron charger's tramp is heard,
And with a warm electric pulse
Columbia's heart of hearts is stirred.

And railroad, telegraph and press,
And commerce with her white-winged fleet
All add new luster to the land
Where wealth and power and glory meet.

And our fair land, our beauteous State,
Is smiling 'neath our Western skies;
Nor Italy, nor Syrian clime,
Can rival her in our fond eyes.

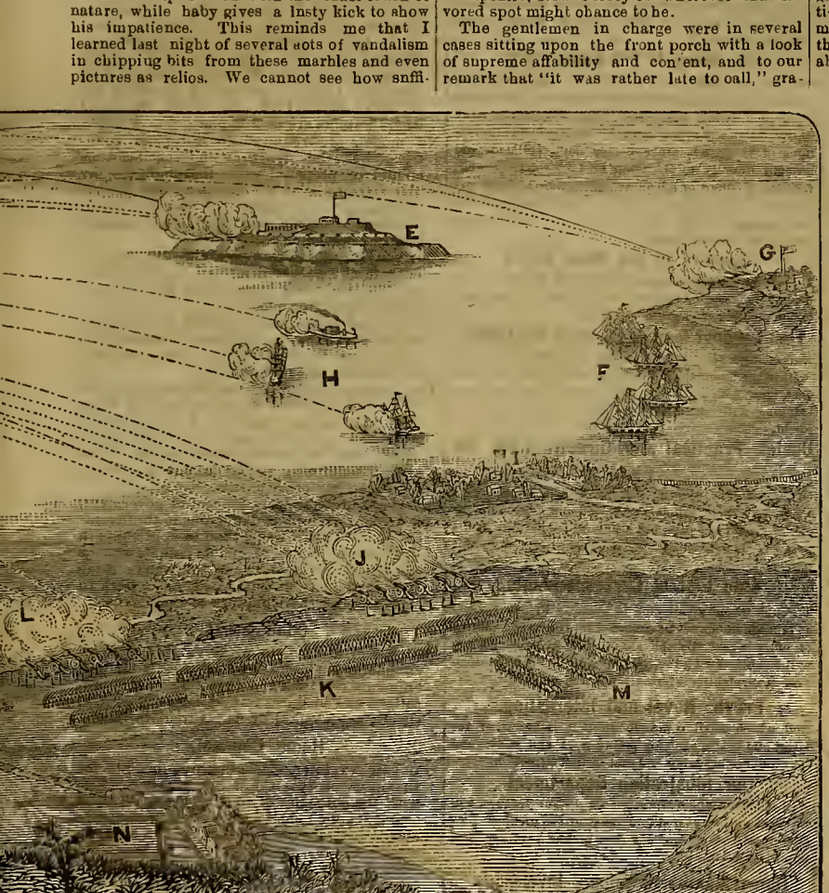
Yosemite's grand wond'rous vale
Will charm as long as earth shall be,
And Shasta's clouded dome shall rise
Till time shall be eternity.

But dearer far than nature's charms
We hold our legacy of fame,
Our heroes of a hundred years,
Our Washington's immortal name.

And thanks to God our country stands
To-day, her starry flag unfurled,
And waves its wond'rous radiance now
Far o'er our grand republic world.

Float on, thou loved and honored flag,
North, South, East, West, from shore to shore,
And our brave eagle, proudly spread
Thy broad, free wings forever more.

A Little Centennial Expedition.—At noon on Tuesday Mr. J C. Temple, of Carthage, Jasper county, Missouri, arrived in this city pushing a wheelbarrow loaded with 50 pounds of lead ore from the mines in his region. Mr. Temple is past the middle age, but is strong and vigorous, and shows few signs of fatigue after his arduous journey of over fifteen hundred miles. In October last he sent out circulars to the Joplin, Oronago and other mines asking that specimens of their ores he sent to the mayor of Joplin, and offering to wheel 50 pounds weight from that city to the Centennial. He started February 28th, accompanied by his son Otto, aged 13, and Thomas Wilson, an Englishman, who wheeled the baggage barrow. The route chosen was by way of St. Louis, thence to Vincennes and Madison, Indiana; Cincinnati, Zanesville, Xania, Columbus, Ohio; Wheeling, West Virginia; Uniontown and Lancaster, Pennsylvania; and thence along the old Lancaster pike to this city. Everywhere the little Centennial expedition was kindly greeted, and in some villages many of the inhabitants turned out and escorted it a short distance on its way. The best distance made on any one day was 27 miles and the journey took 105 days. This was due to bad weather and bad roads. Mr. Temple's ores, which he hopes to find a nook for in the Centennial buildings, comprise splendid specimens of lead, iron, zinc, spar, garnet and black jack. The latter holds 20 per cent. of lead, but some of the specimens are nearly pure.—*Philadelphia Times, June 15th.*



nt in S. F. Harbor, July 3d, 1876.

The Pacific Rural Press

Is a Large and Handsomely Illustrated Agricultural Home Journal; Original, Instructive and Attractive; its varied contents, ably written and condensed, render it popnlar with its readers. We endeavor to make it a credit to the field it occupies, and to every intelligent circle it enters. ENTIRELY FREE FROM POLITICS its columns are filled with cheerful words of encouragement for our Pacific Indnstries and instruction for the people. It extends information of the growing wants and necessities of onr rapidly increasing and progressing agriculture. You can read it with pleasure, for present and future profit; yon can send it with satisfaction to yonr friends anywhere. Its editorials are earnest and its contents reliable. No questionable advertisements darken its pages. It is a journal for rural homes throughout the Coast. It is a handsome home print, without a rival on this half of the Continent. Subscription, in advance, $4 a year.

DEWEY & CO., Publishers,
No. 224 Sansome St., S. F. 3p-tf

"The Public Lands of California."

The demand for thie new work ia steadily increasing, and the more widely that ite merits are becoming known, its nsefulnesa to everyone is becoming more fully demonetrated. The map of California and Ne vada alone is worth more than fifty cents, tha price aeked for the work, and the fact that a glance at ite pagea ehows the leading products, population, etc., of each conuty in the State, headea a list of the surveya of United Statee Land, subject to the homestead and pre-emption lawa of Congress; a correct copy of the lawe of Congreee in regard to locating and holding thia land, etc., rendere it of inestimable value. Ordera sent to Dewey & Co., enclosing fifty cents, will meet with prompt attention, aa it will he forwarded immediately post paid.

To Mining Companies.

A Mining and Civil Engineer of long experience, well acquainted with the superintendence of minee and milla, the projecting and construction of hydraulic worka, machinery, etc., ie open for re-engagement. Apply to Messre. Dewey & Co., of the MINING & SCIENTIFIC PRESE, 224 Sansome street, San Francisco, for reference, or to J. ., Postoffice Box 633, Oakland, Cal

HAMILTON, NEV., May 28th, 1876.

To Messrs. Dewey & Co., Patent Agents:

GENTLEMEN—I write to acknowledge the receipt hy express of the U. S. lettera patent on my invention for breech-loading ordnance, and to tender you again my very sincere thanks for the careful attention you have hestowed upon my application since I first placed it in your hands for the evident great interest you have manifested in it, and for the uniform patient and cheerful courteey which has constantly marked your correspondence in reference to it. I have had some dealings witn other agencies in the same line in times past, and I can assure you that my correspondence with yours hae been more pleasant and satisfactory than with any others, and I shall always take great pleasure in recommending your agency to any and all my acquaintances without hesitation or reservation, aa I should certainly prefer to entruet my own hueineaa in your hands should I have any to traneact in the same line hereafter. Yours, etc., J. R. N. OWEN.

APPRECIATION ABROAD.—We copy the following from the *Mining and Monetary Gazette*, of London, Eng.: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the "United Statee Mining Laws and Instructions, by the Commissioner of General Land Office," taken from our talented contemporary, THE MINING AND SCIENTIFIC PRESS, of San Francisco. The documents have now been issued in a handsomely-bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very useful to those already interested in American minee, and to others who may be tempted to embark in that enterprise in the States."

IMPROVED.—Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS and the RURAL PRESS, now have the leaves of both these sixteen page sheete cut and atitched, which is an improvement that all readers of that otherwise inconvenient form of journal will appreciate very much. Every farmer would be a gainer were he to subscribe for the RURAL. It is decidedly a valuable paper, and the SCIENTIFIC PRESS ia no leis so to mining men.—Inyo Independent.

ANY PERSON receiving this paper after giving an order to stop it, may know that such order has failed to reach ue, or that the paper is continued inadvertently, and they are earnestly requested to send written notice direct to us. We aim to etop the paper promptly when it is ordered discontinued.

UNBROWN.—We have lately received cash at this office without due explanation, ae follows: From Carson, Nev., $4, by express.

The senders will please give full addrees, date of sending, etc.

SEVERAL FIRST-CLASS SEWING MACHINES can he had at favorable rates to the purchasers, if ordered soon, from the Grangers' Business Association, N. E. Cor Davis and California streets, S. F.

BOUND VOLUMES of the MINING AND SCIENTIFIC PRESS from Jan. 1st, 1864, are for sale at thie office at $6 per volume, two volumes a year. Unbound at $3 per volume.

CHOICE VOLUMES.—We have a full new set of *Scribner's Monthly*—ten volumes—well bound, for sale at this office. Price, $2 per volume.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or iasued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It givee short and concise deecriptione of varioue processes and apparatus employed in thia country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illnstratione of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpaesed in his speciality.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Araeniureta, and Gold and Silver Ores generally, with 120 Lithographic Diagrama. 1867.

This work is unequaled hy any other publiahed, embracing the subjects treated. Its authority is highly ateemed and regarded hy its readers; containing, ae it oee, much eesential information to the Miner, Millman, Metallurgist, and other profeaaional workers in ores and minerals, which cannot be found alaewhere in print. It also abounds throughout with facts and inatructione rendered valuable hy being clearly rendered together and in eimple order. It contains 120 diagrams, illuetrating machinery, etc., which alone are of the greateet value. PRICE REDUCED TO $5.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, hound in cloth, $10.50; in leather, $12. Forwarded by mail for 50c. extra, at the MINING ANN SCIENTIFIC PRESS Office, hy

DEWEY & CO.

TRAVELING AGENTS WANTED

For this paper. Experienced canvassers can make excellent wages. None but intelligent persons of good recommendation need apply.

MINERAL CITY, WHITE PINE CO., NEV., May 2d, '76.
MESSRS. DEWEY & CO.—*Gentlemen:*

I have just received Canadian lettere patent for Fuse Lighter. Alao, Canadian lettera patent for the Drill Extractor. I return yon my thanks for the ahle manner in which you have conducted the busineaa.

Youre respectfully, JOHN W. PLATT.

BE MORE PARTICULAR.—We can only make the changes requeated hy the following parties on our mail list, when they, or some one elee, send na their P. O. addreaa. Otherwise we would have to look over from 7,000 to 10,000 names. Frank Becker, O. Seawell, L. Boyer, M. Levie, F. Anson, and Antonia Byros.

We also want the addrese of Wm. Buck.

SAMPLE COPIES.—Occasionally we eend copies of this paper to persons who we believe would be benefited hy enhecribing for it, or willing to aaaiat ne in extending ite circulation. We call the attention of anch to our proepectne and terms of subscription.

MINING AND SCIENTIFIC PRESS

For 1876.

THIS PUBLICATION, SO VALUABLE FOR MINERS, MECHANICS AND MANUFACTURERS,

Will enter upon its THIRTY SECOND Semi-Annual Volume on Saturday, January 1st, 1876. It has ever heen and will still continue to he the aim and object of the publiehere to make the PRESS

A Practical and Interesting Journal.

To this end, we aim, through the conatant watchfulnesa of our editors and correspondente, to sieze upon everything new in the way of mining and the various processes connected with the saving and separeting of the precioue metals, and place the sama before our readers at the earlieet day. It haa been well eaid that

A Newspaper is a Window

Through which men look out upon all that is going on in the world. Our window is a special one, so placed and arranged aa to hring within the scope of its vision all that is going on

In the World of Mining, Mechanics and Science.

Without a paper of this kind, the miner or mechanic is shut up in a small room or shop and can know hut ittle of what is going on in the world around him in relation to his particular calling. In thie age of rapid progress hooks are necesaarily slow and behind the times. It is only through papere devoted to the apecialty which he has chosen that one can he easily apprised of the diacoveriea and improvements which ara conatantly heing made by hie fellow workers, and without a knowledge of which he soon hecomee a leg gard in the race.

The Value to the Community

Of euch publications in disseminating important information, in checking useless and exploded experiments and in instigating important enterprisea, can ecarcely be overreted. Through them the readings and observations of thousands are collected and collated, and brought directly to the shop or table of the reader, without any effort of his own. For a mere trifle of cost he is regularly furnished with an encyclopedia of just the information he needa—an unbound book forever iasning hut never finished.

Nowhere in the Wide World

Is such an aid more needed than hy the miner of California. It is needed alike in the mill, in the mine and in the placer. We have here

The Largest Mining Field on the Globe,

Embracing a variety of minerals nowhere else found within the houndarice of a single field. We have here also, men gathered from every quarter of the globe bringing with them the collective wisdom of the world,

Useful, Practical and Directly from the Field

Of lahor. The ingenieas of hooks has heen hrushed away, and their minds are atored not only with the experience of the past, but also with the practice of the present. It is to this fact that we are indebted for our present

Able List of Correspondents,

Through whom we are ahle to promise to our readers so much that cannot he collected in the mere rontine of office work. By the aid of such help our editors will he ahle, during the coming year, to do more than ever in arnishing information which shall he

Fresh, Novel and Interesting,

And which shall comprise all that is known of the latest and best means for saving gold and silver, and for economizing labor and cost in that direction.

Our Illustration Department

Will still continue to form an important feature, and no effort will be spared to make it of the greatest possihle local and general interest to our readers. The important matter of

Home Manufactures and Inventions

Will also largely occupy the attention of the publishers and editors, and will he constantly encouraged, as an important means of furnishing employment to those who are seeking our shores, and adding to the wealth of the Pacific coast.

The Large and Increasing Circulation

Of a journal thus devoted exclusively to useful and practical information, speaks more in our behalf than anything we could say of ourselves, and is an encouragement to its further increase, especially in these times of trifling and trashy journalism.

The class of readers who are interested in such a publication as this, have no need to he anything more than merely reminded that such journals are necessarily more costly than those of a lighter class, such as are read by the "million" and thrown aside as soon as read. Considering the character and location of the MINING AND SCIENTIFIC PRESS, our rates are as favorable as can posaibly he afforded and do justice to the great industries in aid of which we are laboring.

A Handy Map

Of California and the principal portion of Nevada will be furniahed free to all subscribers who pay one year in advance, during the year 1876. The map is plain, printed on tinted paper, about 16x20 inches, showing townships in California, and the counties, railroads and principal towns in California and Nevada.

We Prepay the Postage

On all papers sent to subscribers in the United States.

SUBSCRIPTION RATES, payable in advance: One year, $4. Sample copies free to those who will assist in obtaining subscribers.

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of goverment, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advise of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F,

The ALLEN ENGINE GOVERNOR.

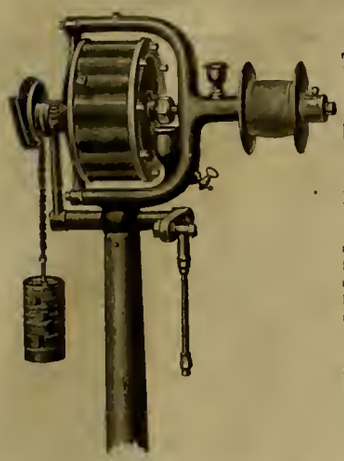

Fig. 1. For Variable Cut-Off Engine.

Uniform Speed in the Working of Steam Engines.

THE SIMPLEST AND MOST EFFICIENT GOVERNOR YET CONSTRUCTED.

ECONOMY and SAFETY.

Especially Valuable with Adjustable Cut-Offs. Capacity of Machinery Increased by Accurate Regulation of Speed.

Direct Saving of Fuel—Great Increase in Power of Engines.

The high rate of speed used acts advantageously in making the Allen Governor very sensitive, and all parts being lubricated, it works with the smallest amount of friction.

The speed of the Engine is maintained equally, without reference to the variations in amount of work being done.

The peculiar action of the Governor, which allows the use of a valve of large area, thereby admitting to the Engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced astonishing results by being attached to old engines, greatly increasing their power or effecting a direct saving of fuel, and in hundreds of instances doing both. In running an engine with the Allen Governor with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Allen's Patent Governor Valve is constructed with a double disc in a tubular frame, and is perfectly balanced, there being no spindle as in the ordinary throttle valve to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, insuring the greatest possible durability.

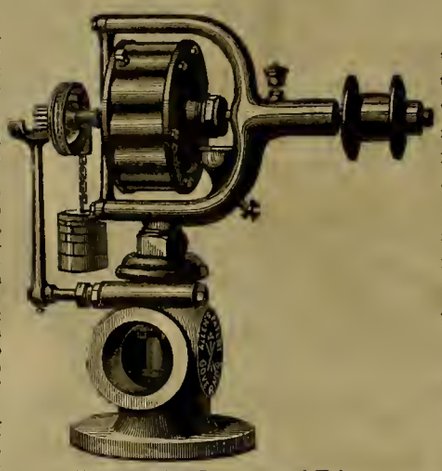

Fig. 2. Allen Governor and Valve.

We have Numerous testimonials from parties who have used this Governor, and watched its workings critically. In all cases the Governor has made the various engines to which it has been applied produce the most profitable results ever obtained.

Fig. 3. Section of Allen Governor.

PARTIES INTERESTED IN STEAM MACHINERY SHOULD EXAMINE THE ALLEN GOVERNOR, WHICH IS NOW INTRODUCED ON THIS COAST FOR THE FIRST TIME. FULL INFORMATION CONCERNING IT CAN BE OBTAINED FROM ILLUSTRATED DESCRIPTIVE CIRCULARS, WHICH WILL BE SENT ON APPLICATION. Address,

PACIFIC IRON WORKS, First and Fremont Streets, near Howard, San Francisco,

HERCULES POWDER.

HERCULES Slaying the Giants.

Hercules, the son of Jupiter and Alcmena, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion he was sent by Eurystheus to execute a very great task, when he found himself opposed by several Giants, among whom were the powerful Giant Geryon, Eurytion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this powder one-half the time is saved that is lost by using any other strong Powder, before you can resume work after a blast.

2. UNIFORMITY.—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.

3. SAFETY—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No Powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.

4. CARTRIDGES.—It is well known that nitro-glycerine has a tendency to decompose by volitilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectually is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally used for cartridges.

5. ECONOMY.—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per cent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. { Hercules X X No. 1, for extreme hard rock. / Hercules X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself:*

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D. 1875.

Present:—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court; Honorable Lorenzo Sawyer, Circuit Judge.

THE GIANT POWDER COMPANY vs. THE CALIFORNIA POWDER WORKS, ET AL., *In Equity, No.* 1,233.—The Court having, on the 22d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said bill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said bill having expired, and the default of said complainant to amend its said bill having been duly entered, and the Court having on the sixth day of October of the said term and year, on motion of C. R. Greathouse, Esq., Solicitor for defendants, M. A. Wheaton, Esq., Solicitor for complainant, being present, in open Court, and declining to amend his said bill of complaint, he having elected to abide by his said bill of complaint as filed in this cause, ordered that a decree be entered herein dismissing said bill.

Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said bill be, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended,

October 18th, 1875.

(Signed) LORENZO SAWYER,
U. S. Circuit, Judge Ninth Circuit.

ENDORSED:—Filed and entered, October 18th, 1875.

L. S. B. SAWYER, Clerk.
By J. F. O'BEIRNE, Dep. Clerk.

Sold by THE CALIFORNIA POWDER WORKS, 314 California Street, San Francisco, Cal.

Also, all grades of Black Powder, Fuse, Shot, Caps, Etc.

Continued from Page 8.

later, as a general in the field, bombarded his own house at Yorktown, and Harrison, afterward the father of a President. Massachusetts sent Hancock, the President of the Congress; Samuel Adams, who shared with Hancock the honor of being excepted from a royal pardon; John Adams, "our Colossus on the floor;" Elbridge Gerry, afterward Commissioner to France and Vice-President of the United States, and Robert Treat Paine, who had acted as public prosecutor after the Boston massacre. Pennsylvania contributed Dr. Franklin, "the genius of the day and the patron of American liberty;" Robert Morris, "the financier of the Revolution," by whose sole credit the Continental army was sustained in its closing campaign, and who was afterward a prisoner for debt; Morton, who had been a member of the "Stamp Act Congress;" Ross, the mediator between the Colonists and the Indians; Dr. Rush, renowned for science and for humanity; Clymer, soldier, student, writer, and prison reformer; the Irishborn Taylor and Smith, and the Scotch Wilson.

Yet the other colonies were represented by delegations hardly less eminent. New York sent Livingston, of "Livingston's manor," the correspondent of Edmund Burke, and one of the framers of the "Address to the people of Great Britain" in the first Continental Congress; Lewis, the Welsh merchant, to whom the British government had given 5,000 acres of land for his services in the French and Indian war; Floyd, who, during the greater part of the Revolution, was an exile from his home, leaving it in the hands of the British: and Morris, afterward succeeded in Congress by his more famous brother, Gouverneur. New Jersey sent Hopkinson, lawyer, wit, and poet—the author of "The Battle of the Kegs;" Dr. Witherspoon, the Scotch clergyman, President of Princeton college; Stockton, a patriot, and the ancestor of patriots; Clarke, known as "the poor man's counselor," though not a lawyer, and "honest John Hart." New Hampshire had chosen Dr. Bartlett, the first to sign the parchment roll; Dr. Thornton, who succeeded Governor Wentworth, and became noting Governor of New Hampshire; and Whipple, who rose from a cabin-boy to be a general, commanding with Stark at Bennington, and under Gates at Saratoga. Connecticut sent Roger Sherman, shoemaker, lawyer, and judge, who had studied while working at his bench, and had become a profound lawyer on borrowed law books; Huntington, afterward President of Congress, and Wolcott, who defended the Connecticut coast against Tryon, and, later, made peace with the Six Nations. Rhode Island sent Hopkins, who had introduced a bill into the Rhode Island Assembly to abolish slave importation, and had at the same time emancipated his own slaves; and Ellery, whose house was burned by the British army as soon as it took possession of the island.

Delaware had elected Rodney, who rode 80 miles, as already stated, to be present at the vote for independence; Reed, who had roused his colony to contribute for the sufferers by the Boston port bill, and McKean, the only man who served in Congress through the whole Revolutionary war. The South Carolina delegates, forming at first the only delegation which had united in opposing independence, were equally united in finally approving and practically sustaining it, Middleton losing his fortune in the cause, Hayward being scarred for life by a gunshot wound, and both, with Rutledge, being imprisoned for a year at St. Augustine by the British; while young Thomas Lynch, who had come from the London Temple to espouse his country's cause, escaped the dangers of war only to be lost at sea at 30. These were all natives of the colony from which they came; but North Carolina and Georgia were honorably represented by what we should now call "carpet-baggers." North Carolina sent Hooper, a Massachusetts man, who had studied law under James Otis; Hewes, the New Jersey Quaker, and Penn, the Virginian, who afterward rallied the mountaineers of his adopted State against Cornwallis. Georgia, again, sent the Virginian, Walton, who had learned to read by the light of pine knots when a carpenter's apprentice; the English Gwinnett, and Hall, of Connecticut, who at first came alone to the congress, and was admitted to represent his district before the young colony had made up its mind. Finally, Maryland was represented by Chase, who, as judge upon the bench, afterward said to a timid sheriff, doubtful about getting some rioters to jail, "Summon me, Mr. Sheriff, and I'll take 'em;" by Paca, who said, after his first session, that the Virginia gentlemen alone seemed able to carry on the Government, so that no one else was needed; Stone, one of the committee that afterward framed the Articles of Confederation, and Charles Carroll, who, lest some namesake should share his risks, added "of Carrollton" to his name.

This is the story of the signing. Of the members who took part in that silent drama of 1776, some came to greatness in consequence, becoming presidents, vice-presidents, governors, chief justices, or judges; others came, in equally direct consequence, to poverty, flight, or imprisonment. "Hunted like a fox by the enemy," "a prisoner 24 hours without food," "not daring to remain two successive nights beneath one shelter,"—these are the records we may find in the annals of the revolution with respect to many a man who stood by John Hancock on that summer day to sign his name. It is a pleasure to think that not one of them ever disgraced, publicly or conspicuously, the name he had written. Rejoicings everywhere throughout the colonies followed the signing.

Then and Now.

Comparisons are not always odious, the old saying "to the contrary notwithstanding." When anybody compares something of his own with something else of his own it is all right; it is only when comparisons are made between things belonging to different parties that they become "odious." Surely in this Centennial year no one can find fault with Uncle Sam if he compares his possessions when he was young and poor with what he has now when he is of age and has become rich. His farm is now a pretty big one and his tenants numerous; but it is not yet all fenced or cultivated, and he has room for many more under his protecting eye.

Just think of how the country has grown since the "original thirteen" started out on their own hook and left their maternal parent fluttering and scolding like an old hen whose brood of ducks first takes to the water. It was a bold venture and fraught with many dangers, but patience, perseverance and energy will always accomplish wonders, as they did in this case.

In 1783 the territory ceded by Great Britain was composed of the country east of the Mississippi river and north of Florida, having an area of 815,615 square miles. This whole territory was not much larger than Alaska, which we bought a few years ago without thinking it much of an accession. Within these 815,615 square miles were the original thirteen States of the American Union, laid out as they are shown on the accompanying map. They were as follows: New York, Massachusetts, New Hampshire, Rhode Island, Connecticut, Pennsylvania, New Jersey, Delaware, Maryland, Virginia, North Carolina, South Carolina and Georgia.

"ONE HUNDRED YEARS AGO"

Compare this small though noble list of States with the country as it stands to-day. The greatest length of the United States, from the Atlantic to the Pacific on the forty-second parallel, is 2,768 miles, and the greatest breadth, from Point Isabel in Texas to the north boundary near Pembina, is 1,601 miles. The northern frontier is upward of 3,350 miles long; the Mexican 1,500 miles. The ocean coast, including the larger indentations, is estimated at 22,609 miles, of which 6,861 are on the Atlantic, 3,461 on the Gulf of Mexico, 2,281 on the Pacific, 8,000 miles including the bays and islands on the border of Alaska, and 2,000 miles on the Arctic sea. The total area of the United States was reported at the census of 1870 to embrace 3,603,844 square miles, inclusive of the territory of Russian America, purchased from the Russian government by treaty of June 20th, 1867, and annexed to the Republic October 28th, 1867, under the name of Alaska. The area of the United States excluding Alaska is equal to 1,942 millions of acres, about one-half of which are public lands. At the census of 1870 the arable land under cultivation was found to be 189,000,000 of acres, or less than one-tenth of the total area. The two black squares shown on the map give the relative area of the United States at the time of the Declaration of Independence and at the time of the celebration of the Nation's Centennial. A glance at them will show more clearly how much the country has grown than any array of figures we could set before our readers.

At the census of 1790 the total population of the United States, white and colored, was 3,929,321. At the census of 1870 it was 38,558,371. At the first census in 1790 there were seventeen States, the largest of which was Virginia, with a population of 747,610, and the smallest Tennessee, with a population of 35,691. In 1870 there were 37 States and 10 Territories. It is stated, on a calculation based on the census from 1800 to 1870, that on June 1st, 1874, the population of the United States was 43,167,000—being an increase of 5,500,000 over the census of 1870. The estimate for June 1st, 1875, on the same authority, is 44,384,000. For June 1st, 1876, it is 45,627,000, while in 1880, the year of the next decennial census, it is calculated that the United States will have 50,850,000 inhabitants.

If the population of the country should continue to double itself as many times in the next century as in the last we should have a census covering 500,000,000 souls—or about a number equal to one-half of the present population of the globe. There is little danger of Uncle Sam extending his farm as rapidly in the future as in the last century, for to do it he would require all the land on this hemisphere, from Greenland to Patagonia, and a million square miles more.

The Celebration in this City.

We print on another page an illustrated account of the main features of the celebration of the Fourth in this city. The chief credit for planning and carrying forward the plan to execution is due to General James Coey, President of the Day. He has labored zealously in the cause, and his efforts will be long remembered as closely allied with the success of the occasion. The other officers of the day are Hon. D. A. MacDonald, Grand Marshal; Col. J. D. Stevenson and Col. Peter Donahue, Vice-Presidents, and Frank J. Murphy, Secretary. The several committees are entrusted with important trusts.

The names of those participating in the pavilion exercises are: Chaplain, Rev. W. H. Platt; Reader, J. E. McElrath; Orator, Rev. Horatio Stebbins; Poet, James F. Bowman. The exercises will be interspersed with music and singing.

The Invitation Committee, presided over by Pay Director Cunningham, U. S. N., met on Monday at the Palace hotel. Invitations were sent as follows: Governor, Cabinet and staff, Mayor, Supervisors and School Directors, ex-Governors, ex-Grand Marshals, Foreign Consuls, Army and Navy officers, Federal and State Judiciary, Federal officers, Mechanics' Institute, United States Senators and Representatives from this State, hold over State Senators from this city, President Grant and Cabinet, General Sherman, General McDowell.

"Overland Chat".—We give in another column a breezy, cheerful letter from "Mary Mountain," who is now at the Centennial exposition. Her letters to the Rural Press, from which we take this one, are principally on domestic and agricultural topics, but that which we copy this week is more general in its character and gives a woman's views of the overland trip.

Preparations for the better ventilation of the deep levels of the Consolidated Virginia mine are being made by enlarging and thoroughly timbering the air winzes in every portion of the mine below the 1500-foot level.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency the following are worthy of mention:

Manufacture of Rawhide. — August C. Kruger, S. F. This is an improved process by which the inventor is enabled to produce a rawhide leather which is thoroughly waterproof. After being put through the process described in the patent the hide is properly stretched, after which it is ready to be worked up for belting, lace leather or for general use. A superior article of rawhide is produced.

Packing Threshing Machines. — Michael Laufenberg, S. F. Manufacturers of threshing machines always set up each machine ready to go into the field before shipping it, and these machines have always been shipped in this condition, because of the great amount of labor required to set them up and the danger of losing some of the numerous parts of which they are composed in case they were shipped in pieces, and also because the manufacturers had no adequate way of boxing them for transportation. The extreme bulk of these machines shipped in this manner renders the cost of transportation quite excessive, especially where they are shipped over long distances by rail, the cost of transporting them to the Pacific coast often exceeding the original cost of the machine. The object of this invention is to pack this class of machinery in a smaller compass, without taking down the sides, which are the most bulky and troublesome to set up. To do this the inventor employs the sides of the machine as a packing case for the interior works of the machine, by setting them close up together so as to leave a space between them and connecting them by short rods or girts. The remaining parts of the machine are then placed between these sides, thus greatly reducing the size of the machine and lessening its cost of transportation, while it can at the same time be readily set up, as the sides remain intact.

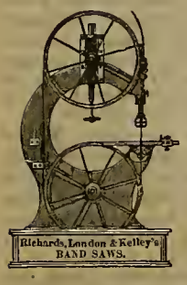
Horse Boot.—Hiram Cook, S. F. The object of this invention is to provide an improved horse boot, such as is used for protecting the hind feet of trotting horses from the effects of over-reaching or forging. As heretofore constructed the boot was fastened to the foot by means of two straps, one of which passed around the heel of the foot, while the other passed under the foot between the hoof and shoe. In the improved boot the inventor uses only the heel strap, and instead of the other he secures to each side of the boot a bent metal clip. One and of this piece of metal is riveted to the boot, and the other end projects inward and passes into the usual notch between the hoof and the shoe, thus keeping the boot from moving or shifting its position. This device is a great improvement on the old method of passing a strap under the foot, because a strap applied in that way will always stretch more or less when it becomes wet, and thus allow the boot to play up and down; besides, it was very troublesome to apply in putting the boot on. But with these metallic clips the boot will always be held firmly in place and no trouble will be experienced in putting the boot on the horse's foot, as the clips will readily enter the openings which receive them. Other means are taken to make the boot exactly fit the curve of the foot.

Cut-off Blast Tuyere Iron.—Isaac S. Van Winkle, S. F. The object of this invention is to provide certain improvements in that class of tuyeres which are employed for blast furnaces and forges, and it consists in so constructing the tuyere that it will have a tendency to convey away from the grates all flux and other substances which will clog them. The grates themselves are so flanged as to present an additional protection and also to prevent leakage of air around them. Combined with them is a valve, which is capable of being adjusted so as to regulate the blast or cut it off altogether. By means of this valve the full opening of one, two or three grates can be permitted, or by turning it one or all of them may be shut off, and the fire can be thus regulated for large or small work, greatly economizing fuel.

Adjustable Mold Board Scraper.—Frank C. Milliken, Santa Cruz. This is a novel construction for scrapers, which is principally useful as a scraper for leveling off ground which is composed of alternate knolls and hollows, where one part will be too dry and the other too wet to make a crop. It consists in the use of a frame having a scraping mold board, which is provided with a mechanism by which it is rendered easily adjustable so as to stand at any angle and scrape deep or shallow, or discharge its load at will.

Improved Surcingle.—P. B. Horton, S. F. This invention consists in applying an elastic or yielding pad to that side of a surcingle which comes next to the animal's body, so that it will conform closely to the shape of the body, and while it serves as a pad or cushion to prevent chafing, it will also give a firmer adhesion which will prevent the surcingle from turning or slipping from its proper place.

California Planers and Matchers, and Wood Working Machinery of all Kinds



California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and *six inch thick*, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. ☞We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

Mortiser.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. ☞*Prices reduced* to 15 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new Illustrated Catalogue. WHELPLEY & STORER'S
Desulphurizing Furnaces, Crushers and Pulverizers for
GOLD, SILVER and COPPER ORES.
State, County and single rights for sale at reduced rates. Machines furnished at short notice.
LEVI R. GREENE, Trustee,
69 Kilby Street, Boston, Mass.

THE O'HARRA
CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
1500 lbs of salt at 1½c	22.50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93⅓

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

W. F. & JNO. BARNES,
Manufacturers of
Barnes' Patent Foot Power Machinery, Scroll-Saws, Circular Saws, Lathes, etc.
The only Foot Power Machine without crank or dead centers. $1,800 to $2,000 per year made using these Machines. Send for Illus'd Catalogue
Rockford, Winnebago county, Ill.

IRON PIPE.

Having been appointed Agents for the Washington Pipe Works, we are prepared to ship from store, Pipe and Fittings at the lowest market prices.

BERRY & PLACE., San Francisco.
TREADWELL'S OLD STAND.

Gloves Made to Order

At prices most economical to customers, at the SACRAMENTO GLOVE FACTORY of I. W. Lusk, Tenth St., between J and K Sts., Sacramento. None but the best quality of California tanned skins used. Ladies' and Gents' colored, plain and Indian dressed riding and common gloves and mittens on hand, or made to order on short notice. ☞Send your size or number and you can order by mail. Satisfaction guaranteed. Ladies, farmers, miners, engineers, and all requiring serviceable gloves are invited to call at the factory.

ERICH G. GAERTNER,
MINING ENGINEER.

All classes of mining properties reported on, consultations had on reduction of ores of all descriptions, plans for furnaces and reduction works furnished, and the construction of them superintended. Ore tests made at the office,

SODIUM AMALGAM.

I am prepared to furnish Sodium Amalgam for $1.50 per pound. Although the price is low, my reputation is a guarantee of its purity. Sodium being now much cheaper than formerly, the miner and millman should have the advantage of it. The temptation to adulterate the article being so great, consumers are advised to call for my manufacture when ordering from wholesale dealers, with an assurance on my part that the quality will be the best. Zinc is sometimes substituted for sodium, to the great disadvantage of the consumer. The following are the tests for pure Sodium Amalgam: Shaken up with water it must be wholly decomposed, the mercury remaining perfectly fluid and the water becoming strongly alkaline.

HENRY G. HANKS,
619 Montgomery Street, San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

California.

While the nation ia celebrating its one hundredth anniversary and rejoicing at the wonderful progress it has made during these years the different States which compose the American Union can each congratulate themselves that they have contributed their share to the general prosperity. Those which are situated west of the Rocky mountains, while they cannot, of course, claim to have assisted in gaining the independence of the nation, are none the less deserving of praise since they have contributed in a marked degree to maintain the prosperity of the people of the United States for nearly a quarter of a century. The boundless agricultural and mineral resources of the Pacific States and Territories, the products of which increase from year to year, are objects of wealth, not only to individuals and the States themselves, but to the nation at large. As real producers, the Pacific States are ahead of all, as their wealth is the product of the ground itself.

California—the word is a synonyme for boundless riches. The "Golden State" is the term by which she is known the length and breadth of the land. The fabulous sums taken from her mines, the marvelous yields of her boundless farms, the variety and abundance of her mineral and agricultural products, have made her famous throughout the world. In beauty and grandeur of scenery she is not excelled, and in variety of soil and climate none surpass her.

The people of the State, whose energy and activity have been the means of so soon placing California in the proud position she occupies, have causes of congratulation to-day aside from those they feel in the prosperity of the nation. Coming to this coast a band of hardy pioneers beyond the confines of civilization and refinement, they battled successfully with the difficulties before them, and have succeeded in building up a State in which not only they but the people of the United States feel a just pride. With all its natural advantages of soil and climate, these effects would not have been produced without the energy, perseverance and intelligence which are the characteristics of the American citizen.

Area of the State.

Rapid as has been the growth of the State in material prosperity, her boundless wealth of resources has been hardly touched. California contains millions of acres as yet undeveloped, and millions of treasure yet to be dug up. The domain comprises 188,000 square miles of territory, and, estimating the population at only 600,000, it contains less than four souls to the square mile, while it is capable of sustaining a hundred. It was estimated that the increase of population last year was about 100,000, and the immigrants continue to pour in at the rate of about 6,000 monthly. But there is plenty of room. When we remember that California contains an area nearly three times as great as the six New England States—greater than all the Middle States with Maryland and West Virginia added—and greater than England, Scotland and Wales combined by 70,000 square miles, we begin to have some conception of the grandeur of our domain; within it about 140 States the size of Rhode Island could be placed.

What California is Doing.

The capacity of this vast area for sustaining population is undoubted. Within the boundaries of the State there are, according to statistics, 3,366,716 acres of cultivated land as well as over 6,000,000 acres enclosed. From an area of over 2,000,000 acres we have an annual product of 29,000,000 bushels of wheat, and beside this we have a yield of about 11,000,000 bushels of barley on an average, per annum. The official records for 1874 showed that with a population of about 726,000 we exhibited a productive capacity of nearly $1,000 per capita. The condition of the savings banks is a good indication of the prosperity of the people. The average balance to the credit of each depositor in the 27 savings banks in this State, on the 31st of December last, was nearly $800, which is largely in excess of that of any other State in the Union or country on the globe. In about eight years our savings banks have paid their depositors in dividends over $34,000,000. These figures show a material prosperity which admits of no denial.

Agricultural Products.

A brief glance at what California has done and is doing for her own welfare and that of the Nation will be interesting at this time. Although she is only in her 25th year, a showing of products and improvements is made almost equaling the hundred years' advancement of other States. We exported last year 4,199,652 centals of wheat and 233,629 barrels of flour. Reducing wheat to flour our exports of that great food staple alone amounted to 1,633,513 barrels. The total products of the State for 1875 were valued at $124,000,000.

The wheat yield since 1856 is estimated at 200,000,000 centals. The wool clip of 1875 was 44,000,000 pounds, and that for 23 years, 300,000,000 pounds. The quicksilver production last year was very large, and was valued at about $2,000,000. It is estimated that the total product of this article in California has been 64,748,893 pounds. The wine product of the State last year was 10,000,000 gallons; the receipts of lumber, 305,000,000 feet; the value of manufactures, $63,000,000; the foreign imports of merchandise, $29,434,000; exports, foreign and domestic, $45,000,000; imports, foreign and domestic, $81,721,245. Our exports of treasure—gold and silver—in 1875, amounted to $73,465,000, or nearly $15,000,000 more than in the previous year.

The Mining Interests.

Of bullion the coast produced, in 1875, $80,889,037—the largest yield yet. Of this, California produced $17,753,151, being ahead of all others, except Nevada, in this class of products. This State held the lead in bullion production until lately, and now Nevada is ahead. It must be remembered, however, that the mines of the latter State were developed to a great extent by California capital, and, in reality, are now owned principally in this State. From 1865 to 1875 the combined product of the two States has been $478,181,520, of which California produced $237,253,151. Nevada is, however, exclusively a mining State, while the majority of the population in California are now engaged in agricultural pursuits. California mining is, however, by no means on the wane, although the surface deposits have been worked out but quite extensive operations are being carried on all over the State. The gravel mines are operated on a scale of magnitude before unheard of, and their yield is in proportion. It takes capital to work these mines, as well as skill and intelligence. In this particular class of mining we have but just begun work and it will be continued on a still more extensive scale for years and years to come. The quartz mines, too, of which there are thousands within our boundaries yet undeveloped, only need more capital to make them yield up their hidden treasures. The assessed value in the 10 hydraulic mining counties of California in 1874-75 was $32,307,523.

Manufacturing Interests.

To San Francisco, the metropolis of this coast, and the seat of the main manufacturing industries, we must look for the progress in manufacture before. A few items from the assessor's report of last year will give an idea of the improvements of this character which have been built up in the city.

There are in the city three artificial stone manufactories, turning out yearly products valued at $137,000; three axle grease factories, producing $91,000; five barrel factories, employing 215 men; five bed-spring factories, annually producing $141,000; five bedstead factories, employing 725 men, aggregate value of products $925,000; two bellows factories, aggregate value of products $27,000; six bedding factories, producing $92,500; five billiard table factories, turning out goods valued at $156,000; twenty boot and shoe factories, employing 2,000 persons, aggregate value of products $2,793,000; two borax works, aggregate value of manufactories $620,000; ten box factories, employing 372 men and producing $980,000 annually; eleven brass foundries, employing 273 men, value of manufactories $1,055,000; breweries, 40, value of manufactures $2,000,000; broom factories, 10, value $200,000; brush factories, 3, value $50,000; candle factories, 2, product $425,000; clothing factories, 8, value $730,000; cigar factories, 120, men employed 9,000, cigars made annually, 95,000,000; chemical works, 5, product $425,000; carriage factories employ 400 men, and products are worth $837,000; coffee mills, 10, value $1,102,000; rope-walks, 3, value $975,000; distilleries, 6, product $1,647,000; flour mills, 8, producing 446,000 barrels annually; foundries, 16, employing 123 men; fur factories, 5, product $245,000; furniture factories, 20, product $1,636,000; glass works, 2, product $270,000; glove factories, 3, product $130,000; glue factory, one, product $325,000; hat factories, 15, product $328,000; hose and belting factories, three, product $114,000; jewelry manufactories, 30, product $827,000: lead and shot factory, one, product $1,000,000; macaroni factories, three, product $120,000; marble works, 21, product $860,000; match factories, six, product $260,000; malt houses, five, product $300,000; oakum factory, one, product $25,000; fruit preserving works, four, product $850,000; powder works, two, product $560,000; rolling mill, one, employs 300 men, product $750,000; silk factories, two, product, $300,000; saw factory, one, product $900,000; sash, door and blind factories, 10, product $2,500,000; silverware factories, four, product $252,000; shirt factories, eight, product $793,000; slipper factories, 18, product $200,000; soap factories, 17, product $513,000; tanneries, 33, product, $985,000; telegraph instrument factory, one, product $75,000; tool factories, six, product $210,500; trunk factories, six, product $240,000; type foundries, two, product $55,000; vinegar factories, eight, product $122,000; windmill factories, four, product $57,000; woodenware factories, four, product $220,000; woolen mills, two, men and women employed, 900, wool used, 3,150,000 pounds, product $2,200,000; watch factory, one, number of watches made 15,000; yeast powder works, three, product $110,000. Assessed value of property in the city in 1875, $126,350,255; improvements, $45,558,161; personal property, $148,659,785; total assessed value in the city, $316,566,205. Population, 250,000.

These factories are only those of the metropolis of the State. Enough have been referred to, however, to give those outside our boundaries an idea of the manufacturing progress of California.

The interior of the State as well as the city is in a prosperous condition, and Californians may well congratulate themselves on living in the most progressive State in the Union. With these feelings, while they rejoice as all good citizens should during the coming holidays at the achievements of the nation in its hundred years, they also feel a just pride in the advancement of their own State in its twenty-five years.

The President's Centennial Proclamation.

The following proclamation has been issued June 26th, by the President of the United States:

This is the Centennial anniversary of the day on which the people of the United States declared their right to separate and assume equal stations among the powers of the earth. It seems to demand exceptional observances. The founders of the Government at its birth and in its feebleness, invoked the blessings of Divine Providence, and the 13 colonies' 3,000,000 people have expanded into a nation in strength and numbers, commanding a position which then was asserted and for which fervent prayers were then offered. It seems fitting that on the occurrence of the hundredth anniversary of our existence as a nation, a grateful acknowledgement should be made to Almighty God for the protection vouchsafed our beloved country. I therefore invite the good people of the United States, on the approaching fourth day of July, in addition to the usual observances with which they are accustomed to greet the return of the day, further, in such a manner and at such times as in their respective localities and religious belief may be most convenient, to make it manifest by some public, religious and devout thanksgiving to Almighty God for the blessings which have been bestowed upon us as a nation during the centennary of our existence, and humbly to invoke the continuance of His favor and protection.

In witness whereof I have hereunto set my hand and caused the seal of the United States to be affixed. Done at the city of Washington this 26th day of June, A. D., 1876, the one hundredth year of the independence of the United States of America.

U. S. GRANT, President.

HAMILTON FISH, Secretary of State.

Our Antipodes.

A wrong idea prevails (if we judge by newspaper gossip) regarding the nationality of our antipodes. China is usually the accused party. But in this case she is innocent.

To us mortals upon the earth's surface, down means in a vertical direction to the earth's center, and real antipodal points are therefore where a straight line passing through the center of the earth cuts the surface. Then it is evident that the antipode of any place in the northern hemisphere must lie in the southern hemisphere. The *latitude* of antipodal points will be the same, but one will be north and the other south. The *longitude* will differ by 180 degrees.

Thus we find our (San Francisco) antipodal point to be in the southern Indian ocean, about 1,000 miles southeast of the island of Madagascar. The point opposite New York is also in the southern Indian ocean, about 500 miles southwest of Australia. The point opposite Peking, China, is in northern Patagonia. A shaft from San Francisco which would reach Peking if continued must (as the miners say) pitch to the west and make an angle with the vertical of about 39¾ degrees. H.

Legal Holidays.

The Governor has, says the Sacramento *Record-Union*, appointed the third and fifth of July as legal holidays, for the reason that the programmes of celebration in many places embraces those days, and calls on all persons to desist from their ordinary vocations on those days and to devote them to the celebration of the Centennial year of the nation. The law under which the Governor acts in declaring Monday and Wednesday legal holidays is found in Section 7 of the Civil Code, and reads as follows: "Holidays within the meaning of this Code are: Every Sunday, the first day of January, the twenty-second day of February, the fourth day of July, the twenty-fifth day of December, every day on which an election is held throughout the State, and every day appointed by the President of the United States or by the Governor of this State for a public fast, thanksgiving or holiday." The Governor calls upon all citizens to devote the three days to the celebration of the origin, progress and greatness of the American people.

THE WHEELER SURVEY.—The House Committee on Appropriations has struck from one of their appropriation bills the item of $50,000 for continuing the geographical surveys under the War Department, in charge of Lieutenant Wheeler. This survey has been in operation since 1871, and has covered and mapped out about 295,000 square miles of country hitherto unsurveyed and practically unknown as regards physical features and resources. The information gathered is of the highest value to the Government and all the interests located in the region traversed, and to all such enterprises as are seeking profitable investment. Besides, a great deal of valuable information has been gathered, and a portion published, embracing paleontology, natural history, agriculture and mineral resources, etc., all of which is of immediate interest.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 27th, 1876.

FOR WEEK ENDING JUNE 20TH, 1876.

CARBURETERS.—James T. Stewart, Los Angeles, Cal.

HOLLOW PARTITION BRICK.—Jules Borie, Oakland, Cal.

PROCESS AND APPARATUS FOR DRYING FRUIT.—William Brown, S. F.

ENDLESS TRACTION RAILWAYS.—Andrew S. Hallidie, S. F.

MACHINES FOR SAWING SHINGLES.—Frank A. Huntington, S. F.

CONSTRUCTION OF WOODEN TANKS.—Edward M. Morgan, S. F.

BEER FAUCETS.—Thomas C. Perkins, Brighton, Cal.

MECHANICAL MOVEMENTS.—Robert Swarbrick Oakland, Cal.

UNDERGROUND TUBES FOR PROPULSION OF CARS. Andrew S. Hallidie, S. F.

TRADEMARK.

LINIMENT.—John Halloway, Wadsworth, Nev.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

THE "Mint" shaft is down 1,125 feet.

THE shaft of the Sierra Nevada mine on the Comstock is now down 1725 feet.

THE pumping engine at the C & C. shaft is being changed from a high to a low pressure, in order to save fuel.

SAMUEL J. TILDEN has been nominated for the Presidency by the Democratic convention at St. Louis.

THE managers of the St. Gothard tunnel works have notified their workmen that they will soon be discharged.

A BOY named Edward Hartshorn was drowned in a pond this week, while trying to save a companion who was sinking.

THE water has been drained from the 500-foot level of the Kossuth mine and work resumed at all points the same as before the flood.

GENERAL CROOK has had the first brush of the season with the Sioux Indians, and came off victorious. He had a horse killed under him.

REAR-ADMIRAL JOHN J. ALMY is detached from the command of the North Pacific squadron July 1st, and ordered to return home and await orders.

THE annual rainfall along the borders of Puget sound, to the southward of Seattle, is from 70 to 100 inches. At Neah bay it often exceeds 120 inches.

THE official order has been issued by the Secretary of War relieving General Schofield from the command of the Military Division of Pacific and assigning him to the West Point military academy, relieving Col. Rueger. General McDowell will take command of the Military Division of the Pacific.

WHILE considering the Sundry Civil Appropriation bill, on motion of Banning, an item of $50,000 was inserted for Wheeler's geographical survey of territory west of the 100th meridian. On motion of Caldwell, an item of $14,000, was inserted for Prof. Jenney's survey of the Black hills.

IN the North Consolidated Virginia mine the flow of water at the bottom of the shaft is still strong, the water tanks hoisting at the rate of 80,000 gallons every 24 hours. A drain tunnel has been started which will tap the shaft at a depth of 172 feet below the surface and thus save the pumping of the water that much. This tunnel is now in 130 feet, and is advancing at the rapid rate of 10 feet per day.

Superior Photographs.—To be sure of a good picture, you have only to patronize G. D. Morse's Palace of Art, at No. 417 Montgomery street, S. F. The publishers of this journal have patronized Mr. Morse for many years, and do not hesitate to say that his pictures are not excelled by any we have seen produced in this or any other country. No one can ask for a better man to patronize than Mr. Morse. He is affable and respectful to all.

Employment Wanted.

Wanted, some kind of employment in the country. Can run a small engine or do many kinds of light work in farming. Reference furnished. Address B., this office.

WASHING freely, with Glenn's Sulphur Soap, parts affected with the obnoxious skin diseases, which have usually been dressed with offensive sulphur ointments, will effect a certain cure without leaving behind any disgusting odor. Sold everywhere.

HASKINS' PORTABLE HOISTING ENGINES, constructed especially for economical use in mining districts, with Compressed Air or Steam, adapted to all classes of underground work and made throughout on the interchangeable plan, so that all parts can be duplicated when desired. Catalogues and Estimates given on application.

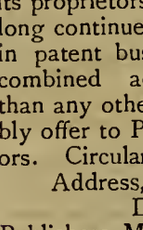
THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address,

DEWEY & CO.,

Publishers MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, San Francisco.

LATEST IMPROVEMENT.



Excelsior Scroll Saw.

Double Treadle, including one dozen Saws, 20 inimitable Fret Sawing Patterns and Prepared Wood to the value of $1. A new device for tightening Saw, Power Drilling attachment, Wrench, Oil Cup and Driver. Speed, 800 strokes per minute. Saws 1½ in. thick. Price, complete, cased and delivered on board cars or at Express office, $12.

SMALL STEAM ENGINES.

With copper Boiler, to drive light Lathes, Scroll Saws, etc. 100 Scroll Work Designs, free on receipt of Stamp.

Saw only, without attachments, $9.

DEETKEN'S

ROASTING FURNACE,

For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 6 to 50 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adapted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

G. F. DEETKEN,

Consulting Metallurgist, Grass Valley, Cal,

Furnace can be seen on application for permit, at Grass Valley.

MESSRS. DEWEY & CO., San Francisco:—Please find enclosed post-office order, for which please send MINING AND SCIENTIFIC PRESS. I have been a close reader of the PRESS for three years, and regard it as the foremost mining periodical in the Union. I am glad to notice the circulation of the PRESS is increasing here and is highly prized by our best mining men. H. P.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Amador Canal and Mining Company—

Location of works, Jackson, Amador county, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1), levied on the eighth (8th) day of May, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
T J Gallagher, Trustee	16	250	760 00
James Rolph, Trustee	22	2500	7500 00

And in accordance with law, and an order of the Board of Directors, made on the eighth day of May, 1875, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of said company, on Wednesday, the fifth (6th) day of July, 1876, at the hour of two o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

J. W. CLARK, Secretary.

Office, Rooms Nos. 1 and 2, 418 California street, San Francisco, Cal.

POSTPONEMENT.—The above sale is postponed by order of the Board of Directors of the Amador Canal and Mining Company to the eleventh (11th) day of July, A.D., 1876, and will be held at the same hour and place.

J. W. CLARK, Secretary.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of June, 1875, an assessment, No. 36, of five cents per share, was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, Room 13, No. 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of July, 1876, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the 5th day of August, 1876, to pay the delinquent assessment, togeth r with the costs of advertising and expenses of sale. By order of the Board of Directors.

C. B. BOGART, Secretary.

Office, Room 13, No. 328 Montgomery street, Safe Deposit Building, San Francisco, California.

Hope Quicksilver Mining Company—Lo-

cation of principal place of business, city and county of San Francisco. Location of works, Cinnabar Mining District, Sonoma County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No 1), levied on the 12th day of May, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the 12th day of May, 1875, so many shares of each parcel of such stock as may be necessary, will be sold at public anction, at the office of the Secretary, 419 California street, room 23, San Francisco, on Saturday, the 10th day of July, 1876, at the hour of 12 o'clock, M., of such day, to pay delinquent assessments thereon, together with costs of advertising and expenses of the sale.

JACOB HARDY, Secretary.

Office, 419 California street, Room 23, San Francisco, Cal.

Manhattan Marble Company of Californ-

ia. Location of principal place of business, San Francisco, Cal. Location of works, Oakland, Alameda Co., State of California.

Notice is hereby given, that at a meeting of the Directors, held on the 23d day of May, 1875, an assessment (No. 9) of three dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary of the company at his office, Noe, 13 and 15 Fremont street San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of July, 1876, shall be deemed delinquent, and advertised for sale at public anction, and unless payment is made before, it will be sold on Monday, the 17th day of July, 1876, at 12 o'clock M., to pay the delinquent assessment, together with costs of advertising and expenses of sale.

L. L. ALEXANDER, Secretary.

Office, Nos. 13 and 15 Fremont street, San Francisco, Cal

Taylor Mill and Mining Company.—Prin-

cipal place of business, City and County of San Francisco, Cal. Location of works, Garden Valley Mining District.

Notice is hereby given that at a meeting of the Board of Directors, held on the fifteenth day of May, 1875, an assessment of twenty (20) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at his office, 607 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-first day of June, 1876, will be delinquent, and advertised for sale at public anction, and unless payment is made before, will be sold on Thur day, the sixth day of July, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

SAMUEL S. MURFEY, Secretary.

Office, 607 Montgomery street, San Francisco, Cal.

Union Consolidated Silver Mining Co.,

San Francisco, June 15th, 1876.

The annual meeting of the stockholders of the Union Consolidated Silver Mining Company, for the election of trustees for the ensuing year, and for the transaction of such other business as may properly come before it, will be held at their office, 311 California street, rooms 3 and 4, second floor, over Ætna Insurance Office (entrance 309 California street), on Monday, July 17th, 1875, at 2 o'clock P. M. Transfer books will be closed July 12th, at 3 o'clock P. M.

J. M. BUFFINGTON, Sec'y.

Umpire Tunnel and Mining Company

Of Utah. Principal place of business, San Francisco, Cal. Location of works, Big Cottonwood District, Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 23d day of June, 1876, an assessment (No. 5) of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, 605 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 24th day of July, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 14th day of August, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. W. DAVIS, Secretary.

Office, 605 Montgomery street, San Francisco, Cal.

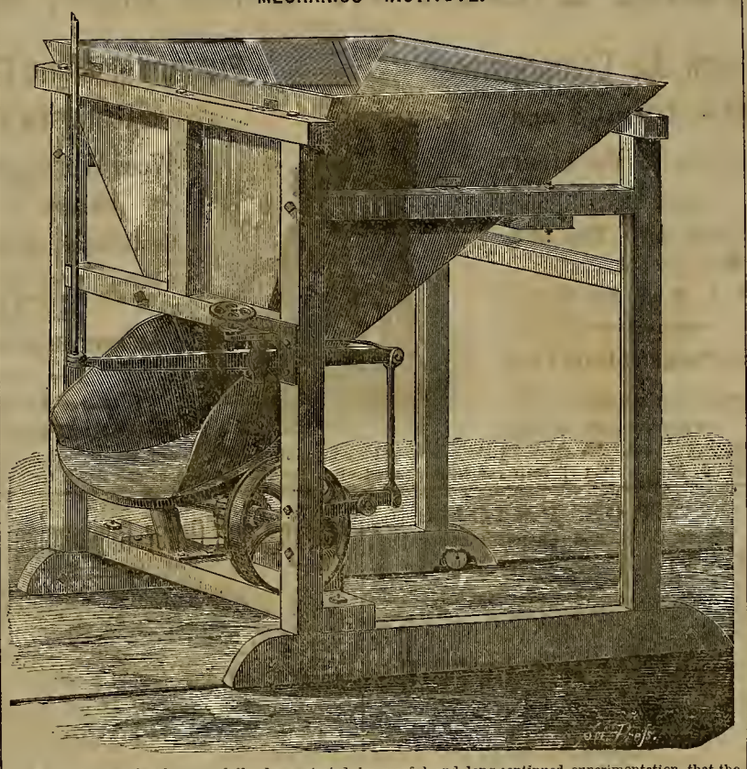
HENDY & COCHRANE'S ORE FEEDER

FOR QUARTZ MILLS,

AWARDED FIRST PREMIUM AT THE TENTH INDUSTRIAL FAIR OF THE MECHANICS' INSTITUTE.



It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the *carrier*, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane, or table, to the line of discharge, and there simply *dropped*. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Juliau Mill, Newcastle, says, of the Table Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."——A letter from Mr. O. C. Belding, of Amador County, speaks in the highest terms of them.——Two of the machines were shipped to the Bunker Hill Mill, Amador County.—— Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen.——Mr. Lachman, of the Soulsby Mill, Tuolumne County, says they work splendid; could not do better.——Two of the machines were shipped to the California Company, Nevada City. ——C. J. Garland, of Mosquito Gulch, Calaveras County, says: "I find them an excellent machine."——S. D. B. Stewart, Supt. Lincoln Gold Mining Company, says they are a perfect success.——O. C. Hewitt, Supt. Keystone Mining Company, says: "I can safely recommend them to all millmen."

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other machine of its class.

Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotels,	Piano Fortes,

Wine Merchants, Etc., Etc.

GIANT POWDER,

Or DYNAMITE,

Manufactured Under ALFRED NOBEL'S Original and Only Valid Patents for

NITRO-GLYCERINE POWDERS.

Both Grades of GIANT POWDER have been much Improved, and we assure those who are engaged in Blasting Operations, that all Imitations of our Powder, such as Hercules, etc., are, notwithstanding any assertions to the contrary, Inferior to the GIANT POWDER or DYNAMITE, which neither in Europe nor the United States has been superseded by any better or stronger Blasting Agent.

Infringers of our Patents are trying to Deceive the Public by ludicrous and bombastic advertisements; but when such tricks are considered necessary, it is invariably done to recommend an inferior article, and no sensible man will be deceived by such advertisements as are issued from time to time in this paper.

We would call attention to the fact that the GIANT POWDER COMPANY employ an able Chemist, whose principal business is to experiment on Nitro-Glycerine Powders, with a view of improving these compounds so as to satisfy the consumer in every respect.

For the liberal support we have received from the public we are very grateful, and respectfully ask a continuance of the same for the legitimate company which obtained its patents at a very large price paid the inventor, and to rely upon our statement that the GIANT POWDER or DYNAMITE has not been equaled by any other Powder, nor is it likely that it will be.

Both grades of Powder are now almost entirely free from fumes, and those which are yet evolved by a blast are not at all injurious to the health.

☞ We beg leave to assure the public that our suits against the Hercules Powder Manufacturers are vigorously prosecuted in the higher United States Courts. ☜

We respectfully solicit orders for our Powder, which is the only safe and reliable Nitro-Glycerine compound made.

SINGLE, DOUBLE and TRIPLE FORCE CAPS,

And the very best Electric Exploders always on hand; also, all grades of Fuse at Manufacturers' Prices.

SCENES IN THE GREAT NATIONAL PARK OF THE YELLOWSTONE, WYOMING TERRITORY. (See Page 32.)

CORRESPONDENCE.

[Editorial Correspondence.]

The Centennial at Philadelphia.—No. 7.

The recent reduction in railroad fares, and the information which has gone out that hotel charges are not exorbitant here, added to the knowledge that the exhibition is now essentially complete in all its particulars, has had the effect to materially increase the number of visitors to the Centennial within the past few days, and the grounds are now daily thronged in their every part with great multitudes of people, who come hither from all parts of the country to witness the wonders of mechanism and other handicraft which go to make up the great panorama of the world's progress for the last hundred years which is here presented. The picture shown could never have entered into even the wildest dreams of the sages and seers who planted the seed, the ripe fruit from which we are now enjoying. Besides our own, sixteen foreign nations are here represented and their industries illustrated, to all but one of which I have made more or less allusion, and to that I will now call attention as the last but most important.

The British Exhibition.

Great Britain and her colonies occupy about one-third of the entire foreign space in machinery and agricultural halls, and about one-quarter of the same in the main building, where the miscellaneous exhibits of all nations are shown. Her contributions of machinery are not as numerous or varied as the American visitor had expected or might wish to behold. She is noticeably deficient in machine tools, in which particular the United States exhibit is remarkably full. A comparative exhibit of machine tools by England and the United States would have offered a most interesting and instructive study. But England, as a general thing, has brought only those articles with which she can best compete with our people. Her exhibits are largely of a heavy character. She shows but little that is small—much that is wonderful and useful. Among the wonderful we may especially notice her exhibit of

Heavy Armor Plates and Tested Samples.

In the manufacture of heavy masses of metal England excels the world. Her well known steam hammer plant for forging 81-ton guns affords an illustration in this direction. Her immense plants for forging heavy armor plates furnish another. These huge masses of rolled iron are among the most wonderful exhibits at the Centennial, while the tested samples, exhibiting the effect produced upon them by the impact of steel and chilled iron balls from her improved Armstrong guns, show what progress the so-called science of war is working among our cousins over the water.

In this exhibit we have, first, a fine specimen of armor plate, eight inches thick, and cut from an original plate 25 feet long by seven and one-half wide. The welding is so perfect that it is difficult to detect from its polished edge that it was not rolled out from one massive bloom. Near this is a smaller section cut from a plate 16 feet long by five and one-half wide and 21¼ inches thick. One side of this plate has not been trimmed, but has been left to show of how many layers of plate upon plate or different blooms it has been built up. The ragged, unfinished end shows them distinctly, while a finished edge shows the perfection with which the work has been done. Near by we have another plate 11 inches thick, which has been tested with a seven-inch rifled gun, loaded with an elongated chilled shot, discharged with a distance of only 30 feet between the muzzle and plate. Five shots appear to have been fired, four entering so as to make only one large cavity; a fifth was delivered a short distance apart, showing what a single ball can do when fired from a modern rifled gun against a mass of solid iron. It had bored its way fully six inches into the solid wrought iron, forcing back the iron so as to form a jagged projecting fringe all around it. A further interesting exhibit would have been the shot itself or its fragments after it had performed its mission. None of the shots had passed through the iron; but where the four shots had been so fired as to make a single cavity the concussion had produced a slight bulge in the back of the plate. These plates are exhibited by Messrs. Cammel & Co., of Sheffield, England. Messrs. John Brown & Co., of Sheffield, also exhibit several plates which have been tested with results similar to the above. Another firm exhibits a splendid 14-inch plate which nobody has attempted to punch. These wonderful exhibits, in connection with the mammoth Krupp guns in the German exhibit, near by, are constantly being stared at by gaping crowds of all classes of our people, with the awe and amazement usually attributed to the provincial alone. But one must be to the manor born, so to speak, to be able to look upon such wonderful triumphs of human skill without a shudder at their sight and an inevitable reflection upon the terrible game of strength and skill which now constitutes the artillery practice of war.

It is with real pleasure that we turn from this exhibition of the skill of man directed in the way of producing agencies destructive of life and property to the more congenial and useful

Display of the Arts of Peace.

That which comprises most of the wonderful with the useful in this direction is the "Walter web printing machine," so called. This printing press is really one of the wonders of the exhibition, and attracts most marked attention. It stands on the fractional portion of the section in the English exhibit, marked 8 in the diagram which appeared in the PRESS two weeks since, so as to bring it as close as possible to the American presses shown in the sections marked A. Its only competitor is the Bullock press, on which the *Tribune* is printed, and which is similar to the one on which the *Evening Post* is printed in San Francisco. As much as the Bullock press is in advance of the other American presses, it is far from being abreast of the Walter press. The Walter press has its forms stereotyped and fitted to a small cylinder the same as with the Bullock press, and prints both sides, rolling off the paper continuously from a cylinder, printing it on both sides and cutting and delivering it in two piles, at the rate, as the gentleman in charge assured me, of *fifteen miles of paper per hour*—almost up to the average speed of a railroad train! Even at that great speed it is wonderful with what precision and neatness it does its work; it cannot be excelled in that particular by any cylinder press of any make. The English must certainly lend us in this direction.

The next most wonderful as well as useful exhibit in the English department is a Jacquard silk loom from Coventry. This loom is set to weave portraits of Washington, Victoria, Shakspeare, Grant and others. It weaves 20 portraits of the same individual at one time, which are turned off in a continuous ribbon and cut apart and sold at a dollar each, almost as fast as they are woven. It is really wonderful to observe how perfectly it does its work—almost equal to the best work of the engraver. Eight different colors are used in Washington's portrait. The loom scarcely requires any attention at all. There is an American Jacquard loom in the United States department, also set to weave portraits.

A Coal Cutting Machine.

An exhibit of much interest to the coal mining fraternity hereabouts is the coal cutting machine of William Baird & Co. This machine ought also to attract the attention of the coal mine managers of the Pacific coast, for it or something similar must soon be introduced to save the present waste of coal and reduce the cost of getting it out with the comparatively high cost of labor there. I cannot learn that any such device is used in any American coal mine, although there are a large number used in Great Britain with great success. It would be difficult to describe the machine without diagrams. It may be sufficient to say, in this connection, that the machine is very simple and easily handled. It works by compressed air, and cuts its way through a seam of coal to a depth of from three to five feet. It first makes a cut under the seam to any desired length along the vein, then cross-cuts until the projecting section of coal, having no support, falls of its own weight, or if necessary is thrown down in a large mass by driving wedges over the top of the seam. The machine will cut through from 300 to 350 feet of a three-foot vein in from eight to ten hours, thus throwing down in that time, in the very best possible condition, 75 to 90 tons of coal, requiring the attention of only two men and a boy. The gentleman in attendance is a son of the inventor, and explains its working so as to be readily understood by any intelligent miner. It is somewhat singular that these machines have never been introduced into this country. But we presume this exhibit will be the means of effecting so desirable an end. Haines & Payton also exhibit a coal cutter.

The Aveling and Porter Road Locomotives, Etc.

The Messrs. Aveling & Porter exhibit several of their celebrated road locomotives—one of which, some of our readers will recollect, was imported into California a few years since, but was never considered a success there. It is now, I believe, laid up in a storehouse near the Pacific Mail company's wharf. It is said that one reason why these machines have never succeeded in the Atlantic States is on account of the inferiority and uneven character of our roads. Such an objection, at least so far as the unevenness is concerned, cannot account for the impracticability of such machines on the valley roads of California. Notwithstanding all that has been said in regard to their use in Scotland and the north of England, we are inclined to think they are not very common there. They present every evidence of strength, durability and handiness for use; but were it not that this is an age of progress in almost everything, we should be inclined to think the road locomotive was an impractical idea.

In connection with this exhibit, several steam cranes are shown, which are worthy of special consideration by all parties having heavy bodies to move short distances. These cranes are capable of lifting from three to five tons, while the work of steering, driving and working the crane is performed by one man, stationed on the foot-board. They have a working circumference of about 150 feet. These cranes have been of very great service in lifting goods and machinery into place in machinery hall, and are pronounced most superior and efficient machines. They have proven the most useful of all the visiting machines on the ground, having promptly made themselves at home there and gone to work.

Other English Exhibits.

One of the most notable exhibits in this direction which England has brought us is a fine plant of sugar machinery from Glasgow, designed for the production of raw sugar on the plantation. Then we have improved machines for working wool and cotton in operation, performing the actual work of carding, spinning and weaving; also machines for making and shaping confectionery. What appears to be a very superior mode of securing picks upon their handles is shown, which I presume will be placed on exhibition at the Mechanics' fair, in August next. Mining men will do well to examine these picks. A metallic shield is first slipped on to the handle, and the pick is then dropped on over this shield and secured in place by a simple and apparently effective device. We have also calico printing machines, hydraulic presses and a few machine tools for heavy iron work. Several pumps are also shown in the hydraulic annex.

In machine tools the English exhibit, as already stated, is rather deficient. We have a few for metal and heavy iron work; but nothing at all, comparatively, to what is shown by the United States. Perhaps such an exhibit could hardly have been expected from a country where such tools are so little used to what they are here.

Several useful inventions are shown in models, among which we may mention prominently a railroad junction, fitted with a patent system of interlocking switches and signals for working on the block system. A model is also shown of a device for rendering this system automatic, by means of an electro-mechanical machine, which operates the levers without the interference of any other agency than that of the approaching train itself. With the increasing demand for faster passenger trains, and the rapidly accumulating business on some of our more important roads, improvements in this direction, calculated to afford better protection for human life, will be gladly received and their merits carefully considered.

There are many other minor matters connected with the English exhibit which we should notice, did space permit; but with what has already been written we must close our notice of foreign displays in machinery hall, until we come to a general comparative summing up. My next letter will be devoted to the United States exhibit of machinery.

W. B. E.

Centennial Grounds, June 11th, 1876.

No. 8.—American Department.

My last letter brought the notices of foreign exhibits in machinery hall to a close, and I now propose to pass in brief review our own exhibitors, previous to instituting any inquiry in relation to the comparative merits of the two. By reference to the diagram it will be seen that fully three-quarters of the entire space in mechanics' hall is occupied by the United States; this space, however, is largely filled up by the frequent repetition of the same classes of machinery by different exhibitors, the tools and implements varying only in the modifications of construction adopted by different builders. Previous, however, to reaching the tools, I would ask the reader's attention for a moment to a very interesting exhibit from the

Midvale Steel Works.

These works, located about five miles from Philadelphia, may very properly be regarded as the model works of the kind in the United States, and are under the management of Mr. William Sellers, one of the most thorough and progressive mechanical engineers in the country. This exhibit, moreover, forms the basis of that which follows; as all the iron and steel which enters into the construction of the tools which Mr. Sellers' exhibits, as well as those of several other exhibitors, is made at these works. The display is located in the second tier of fall sections from the south wall of the build ng, and adjoining the English exhibit. We have here a most interesting and instructive show of heavy cast steel forgings, tool steel, ingots for rails, car wheels, axles, etc. They show one steel ingot which weighs 7,000 pounds. They also make a very interesting exhibit of the process of manufacturing car and locomotive wheels; the work is shown in every state of its progress, from the original bloom to the complete wheel, some eight or ten stages. The mode of casting is very peculiar and careful, necessarily so from the importance of the manufacture, as one on which, more than any other one thing, depends the safety of railroad traveling. The same is shown in regard to the manufacture of car axles. So successful has this company been in establishing, from tests and practical wear, the reputation of its wheels and axles, that the Pennsylvania Central, the most extensive railroad connection in the world, refuses to use either wheels or axles for its passenger cars from any other firm. The Siemens-Martin steel is used for tires and other heavy purposes, but for tools, crucible steel is employed. At some future time I hope to find leisure to visit these works and describe them at length, with illustrations.

An Improved Rotary Puddler.

At the time of my visit to this exhibit, workmen were engaged in putting into place a mammoth iron cylinder and furnace, which I was informed was an improved rotary puddler, upon which Mr. Sellers has recently been at work. This furnace is to be exhibited in motion, although not charged with the molten metal as when in actual work. It seems to be characteristic of Mr. Sellers that he must always be inventing—improving everything that comes into his hands. Thus, he is not satisfied with the Danks or any other machine puddler, but must have a Sellers puddler; and if we are to judge in this instance from his past record, he will give us something really valuable in this direction. A perfectly practical machine puddler would be one of the greatest boons which could be conferred upon the producer of iron. The Danks puddler appears to be a success; but if Mr. Sellers can furnish us anything still better, we should like to see it. The employment of the cheapest and best methods of producing iron is the only means by which this country can hope to successfully compete with foreigners in the industrial arts generally.

Machine Tools.

The general exhibit of machine tools in this building is the most remarkable of the kind ever brought together. There are a large number of exhibitors—some twelve or fifteen in number. The first and most extensive collection on the floor as we pass down the building is that made by Sellers & Co. Mr. S. was one of the few Americans who had the enterprise and courage to make anything like an extensive exhibit in this line at Paris and Vienna, and as a reward for his skill and enterprise and the superiority of his exhibits, he was honored at both of those places with the highest awards made—at Paris with the grand gold medal and at Vienna with the diploma of honor. The latter was more than a mere acknowledgement of superiority in skill, for it was also designed to convey the idea that its recipient had achieved eminent merit in the domain of science and the application thereof to the advancement of the intellectual, social and material welfare of mankind. That award may be considered the highest honor ever conferred upon any industrial pursuit.

As a result of that exhibit, many of the machine tools constructed by this house have been adopted as patterns by machine tool makers in Europe; and thus American ideas and practice, the germs of which were drawn from the old world, are gradually finding their way back again, enlarged and improved by their manipulation here.

The tools exhibited by this firm here are substantially the same as those shown in Europe; but with the never ending desire of their manufacturer to improve and keep ahead of all competitors, he has since, from time to time, introduced such improvements as he has thought would give them additional value. Tools, like everything else capable of modification, are constantly undergoing changes; but unlike many other things brought under the universal influence of change, these useful devices for aiding man in his labors are usually bettered by the process, for the reason that any alteration in a tool that does not improve it is promptly discarded and can never win its way to popular favor. The smallest changes often work wonders in a tool before thought perfect; hence the ingenuity of man is never at rest. A little here and a little there—a thought here and an inspiration there—adding and taking away, is the history of every invention which comes from the brain of man.

We have no space to describe or even make the briefest mention of all the exhibits, and can only refer in a very few words to the most notable ones: One of the first that attracts the attention of the visitor is a gigantic planing machine, capable of finishing with the utmost precision a mass of iron ten feet high, ten feet wide and thirty feet long! The machine is also so constructed as to be capable of finishing an object on three sides at the same time. This invention is flanked on either side with smaller tools of the same description. Near by is a large plate shearing machine, a tool which cuts through inch iron as readily as ordinary hand shears cut paper. This machine will cut inch plates five feet in width at a single clip. It is used for cutting and trimming long sheets of iron and for bridge purposes, or for columns and girders. Near this exhibit is a steam hammer the pattern of which was originally borrowed from Morrison, of England, but which has been greatly modified and improved by translation to our American shops. Three sizes are shown, of 300, 1,500 and 5,000 pound hammers. Even the largest of these machines may be used to forge the heaviest masses of iron or crack an almond, when held between a lady's thumb and finger, without danger to her hand.

Immense hydraulic presses for forcing locomotive wheels upon their axles and large lathes for turning them are also shown, as well as numerous smaller ones. Another very interesting machine, and quite a novelty in its way, is an automatic gear cutting machine for cutting bevel and spur wheels. This is a great labor saving machine, and, we believe, is one of Mr. Sellers' own inventions. There is also a new and peculiar machine for shaping hexagonal nuts, the work which is of accomplished by six cutters, which finish the nut with a single cut upon all its sides at once. Mr. S. exhibits a cylinder boring machine, which it is claimed will finish complete a locomotive

(Continued on Page 30.)

MECHANICAL PROGRESS.

New Rules of the English Patent Office.

The Lord Chancellor, the Master of the Rolls, the Attorney General and the Solicitor General, being four of the Commissioners of Patents for inventions under the patent law amendment act, 1852, have just issued the following, for which we are indebted to *Iron:*

I. The rule of the Commissioners, dated the 17th December, 1866, requiring every applicant for letters patent to deliver with his provisional or complete specification an abridgment of such provisional or complete specification, shall not remain in force after the 30th day of June, 1876.

II. The latter part of Rule III. of the third set of rules and regulations of the Commissioners, dated the 12th of December, 1853, (viz., "The extra copy of drawings, if any, left with the same, must be made as heretofore and according to the directions contained in Rule III. of the Lord Chancellor, dated the 1st of October, 1852,") shall not remain in force after the 30th day of June, 1876. From that date the following shall be substituted therefor: The extra copy of drawings left with the same must be made on good white smooth-surfaced drawing paper of the same dimensions as the parchment drawing. All the lines of the drawing must be absolutely black, India ink of the best quality to be used, and the same strength or color of the ink maintained throughout the drawing. Any shading must be in lines, clearly and distinctly drawn, and as open as is consistent with the required effect. Section lines should not be too closely drawn. No color must be used for any purpose upon this drawing. All letters and figures of reference must be bold and distinct. The border line of the drawing to be one fine line only. This drawing must not be folded, but must be delivered at the office of the Commissioners either in a perfectly flat state or rolled upon a roller, so as to be free from creases or breaks. In all cases where the original drawing on parchment is colored, there must be left, in addition to the above copy, another copy colored.

III. The latter part of Rule IV. of the third set of rules and regulations of the Commissioners, dated the 12th of December, 1853, (viz., "The extra copy of drawings, if any, left with the same, must be made as heretofore, and according to the directions contained in Rule II. of the Commissioners, dated the 1st of October, 1852,") shall not remain in force after the 30th day of June, 1876. From that date the following shall be substituted therefor: The extra copy of drawings, etc., [worded as in paragraph II. above].

The notice to the public is worded thus: The Commissioners of Patents having decided that the drawings accompanying the provisional, complete and final specifications of 1876 and subsequent years, shall be copied by the process of photo-lithography, the regulations prescribing the mode in which the extra copy of such drawings shall be prepared must be strictly observed, in order that correct copies may be made. All specifications and drawings filed in pursuance of letters patent should be left at the office of the Commissioners at least six days before the expiration of the time for filing the same, in order that the officers may examine the extra copy of the drawing, and ascertain that it has been prepared in conformity with the rules.

How the Bryant Vase Was Manufactured.

The first, solid piece of silver was all that the workmen had to begin with; and this plate, first with wooden mallets and then upon the arm of an anvil with hammers, was beaten into the form of a bowl, not without great care and long labor. Then began the nicest and most difficult part of the task—working out from the surface by the repousse process the flowers and projecting portions of the design according to the model in wax which had already been made of the whole. What are called the formative processes in all metal working may be classed under five heads—casting, bearing hot, beating cold, electrotyping and cutting away by erasive tools. All these methods to a certain extent have been employed in this vase; but the chief method has been that of beating cold, or the repousse system, of which Cellini was such a master, and which the greatest metal sculptor of the present day, Morel Ladeuil, has reproduced with such effect as to make it the part alike of wisdom and of modesty for other artists to follow it, as the makers of this vase have done. The repousse style begins its task by working the surface from within outward by means of snarling-irons, which have two horns very much like those of the anvil, and, like an anvil, they rest upon a block. One of these horns is made to touch the proper point on the inner surface of the vase, and the blow is given not directly upon this horn, but upon that opposite, which, when struck with skill, sends its vibrations to the other horn, which is in contact with the metal. By these vibrations the metal is raised to the due elevation so gradually, and yet so vigorously, as to secure the result without breaking or weakening the metal. When the bowl is thus shaped from within to the requisite form for the intended projections, it is filled with a composition of pitch and other ingredients; and then the workman changes his course, and begins his more difficult task of working the projecting surface into due form from the outside. In this way all this exquisite flower work was produced, and every blossom and leaf, every ear of corn, lily and primrose, was wrought by the eye and hand of the artist, and each thing bears the mark of his mind and his touch. The work requires generally several repetitions of the process, and the bowl is emptied and filled again. The medallions were made in the same way, instead of being cast from the wax, which is much the easiest, but does not leave the same fine lines and vital expression. In some parts of the work, as in the handles, whose form and figures did not allow repousse work, casting was resorted to, the designs being modelled in wax from studies of natural objects.—*Dr. Samuel Osgood, in Harper's for July.*

Curious Bursting of an Iron Tank.

One of our English exchanges describes an accident of an extraordinary nature, which occurred one Saturday, at St. George's hospital, by which several of the patients met with severe injuries, and from the effects of which some of the students at the institution are suffering. At the top of the northern extremity of the building, fronting Grosvenor place, there was a cast iron water tank. The water was supplied from an artesian well in front of the building, and the tank, when filled, was capable of holding nearly 20 tons, which served for the ordinary requirements of the hospital, and was further intended to be applied in case of fire. Immediately under the tank were wards for the reception of women and children. About a quarter past eleven in the morning a nurse in one of the wards perceived water penetrating the ceiling, and before there was time to give an alarm, a loud crash was heard above, and in another minute there was a deluge of water, and one side of the tank came with tremendous force through the roof into the ward, thence into another underneath finally depositing itself on the ground floor. Three of the iron bedsteads, with their occupants, were precipitated to the bottom, and in two or three instances the suffering inmates were washed from their beds. From the students' room many escaped in terror by the windows. The patients screamed with alarm, and were with difficulty appeased. After the alarm consequent on the falling of the tank had partially subsided an additional fright was experienced. There was a large "lift" in connection with the building, worked by hydraulic power, and as soon as the water had spent itself the ponderous machine fell from the top of the building to the bottom with great violence. The tank was built six years ago by Easton & Co., of Erith. It was of iron plate, five-eighths of an inch thick. The surveyer to the hospital, Mr. Salter, made his annual report on the buildings a fortnight ago, after inspecting them, and found no fault in the tank. An inspection of the broken tank shows that it is, roughly, 12 feet deep and 10 feet square. It is calculated to have contained at the time of the accident 25 tons of water, or 5 000 gallons. Its total capacity was 8,000 gallons. The east side of the tank is that which has given way. The iron has not parted from the rivets, but there is a large, jagged hole broken in it, approximately a circle with a diameter of six feet. It is not one plate that is broken, but several. All are on the east side. The tank was placed on iron girders, and these rested on brick supports.

AIR CASING FOR STEAM BOILERS.—Mr. Stone, says the London *Mining World*, has discovered an ingenious contrivance for the air casing of steam boilers. This invention has already received considerable attention at the hands of various manufacturers, and is destined, when it is better known, to receive still more. Everyone acquainted with the manipulation of steam boilers knows how important it is to prevent as little heat as possible escaping by radiation into the surrounding atmosphere. It is the waste of heat by radiation that chiefly makes boiler rooms and stokeholes hotter than it is desirable they should be. To prevent this, as well as to secure some other important advantages, to which we shall presently advert, Mr. Stone comes to the front with his patent for air casing steam boilers, the nature of which it is very easy to understand. He places the casing over the boiler, but leaving a space of from two to three inches between. All the air supplied to the stokehole passes over the boiler, but under the casing, and so arrests radiation. The air, in fact, becomes heated as it passes in, and effects a considerable economy in regard to the fuel. The casing is made as air-tight as possible, and covers the whole of the boiler, with the exception of the part not enclosed by the brickwork setting. At the end of the furnace there is a similar opening, provided with a faotail regulator, or damper, which can be used as desired. The steam box is also enclosed, but airways are provided in the casing opening to the furnace. The introduction of hot air instead of cold has important results with regard to the consumption of fuel.

A LONG GAS PIPE.—There was, says the *American Manufacturer*, a very interesting and conclusive experiment made with the use of the three-inch pipes of the Columbia conduit company, before they were in use for the transportation of oil, by connecting them with the small gas well at Millerstown. From the time the gas was turned in to the time it ignited at Hamerville, Alleghany county, 32 miles from the well, was 22 minutes; of course it was impeded by the air, which had to be forced out of the whole 32 miles of pipe in that time. The amount discharged was at the rate of 161,000 feet per 24 hours, the noise or roar of the discharge alarming the people living in the vicinity, with no perceptible difference in the flame between the discharge end of the pipe and at the well. The pressure at the discharge was 49 pounds, and at the well 55 pounds, a difference of only six pounds per inch after the connection with the well. This, of course, is not in conformity with the theories and demonstrations of scientists, but the experiment was conducted under the care of two experienced engineers, namely, J. H. McElroy, of Pittsburgh gas company, and R. Young, of Allegheny gas company, and the facts can be relied upon. It looks as though some facts would have to be changed, or some tables and books on pneumatics and hydraulics will have to be revised.

BOILER EXPLOSIONS.—The number of boiler explosions in France from 1868 to 1872, with cause of same and number of killed and wounded, is given as follows by the *Deutsche Ind Zeitung:*

	1868.	1869.	1870.	1871.	1872.	Total
No. of explosions	24	18	13	22	21	98
No. of killed	31	22	10	20	13	96
No. of wounded	33	20	16	25	32	126
CAUSE.						
Neglect of attendant	19	12	7	8	13	62
Faulty construction	0	3	3	0	6	20
Faulty setting up	2	2	2	2	0	8
Unknown	3	1	1	8	0	8

DANGER OF PASSING RAILROAD CURVES.—A new engine has been invented by Mr R. H Gilbert, the projector of the Gilbert elevated railroad, intended to carry passengers at the rate of 40 miles an hour. The driving wheels are only three feet in diameter, while the load required to secure sufficient adhesion to the rails when drawing heavy trains consists of water carried in a tank low down between the wheels, which water can be easily discharged at the stations when the train is not so heavy as to require this extra load, and it is claimed that this engine can turn the most abrupt curves without danger to train or railroad track.

SCIENTIFIC PROGRESS.

Perfumed Newspapers.

Alex. S. Macrae, of Toronto, Canada, has discovered a process by which perfumes can be permanently and economically adapted to the manufacture of paper, so as to give it style, freshness, attractiveness and finish, without in any way increasing the cost of its production.

John Riorden, of the Merriton paper mills, Canada, which produce ten tons a day, chiefly printing paper, challenged Mr. Macrae to so perfume his paper during manufacture that it should go through the printing press, and yet be circulated in the usual newspaper way—scented however, to the satisfaction and delectation of the public. The challenge was accepted and the trial came off on May 11th. The process was conducted by Mr. Riorden and his brother, assisted by their men, under the direction of the inventor. The newspaper selected was the St. Catherines *Journal*, the proprietors of which were served with the usual wrapped sheets, without intimation as to their having been perfumed. When the *Journal* appeared on the 17th—six days after the process—considerable interest was manifested by their readers as to the aromatic atmosphere their presence engendered. Every newspaper resembled a bunch of flowers; every hand that touched them was more or less scented; every room in which they were read became fragrant.

After the paper was scented it went through the drying, calendering, reeling, and cutting machines; and was sorted and wrapped ere it left the mill for the publishers. It then had to pass through some miles of fresh air and damp; to be opened at the printing offices on the day of issue, exposed to the drafts and smells inseparable from the operations of work people; to be damped, inked, pressed, and printed; and lastly, to be delivered in the open air, in single sheets, at numerous places and at various distances.

It is claimed that the scents are so powerful and so condensed that enough "invisible perfume" can be held in one hand to keep a mill, however productive, going for a whole day. The perfumes are said to be perfectly odorless and harmless, and their cost not more than one per cent. on the cost of production! The perfuming process does not interrupt the paper process for a single moment, and the longer and more compact the paper is kept afterwards the more fragrant it becomes; which is of great importance in bound books.—*Paper Trade Journal.*

Formation of Anthracite Coal.

The Shenandosh (Pa.) *Herald* has discovered a phenomena which it calls a "wonderful discovery and revelation of the process of the formation of anthracite coal." The affair is very interesting, be it what it may be, and we quote as follows:

We have before us now on our table a specimen which is one-half anthracite coal and the other half a solidified sediment that four years ago was all soft sediment. For over four years there has been in use in the Indian Ridge shaft of the Philadelphia coal and iron company, this district, a wooden pipe, about six inches in diameter, made of inch boards nailed together, which served to carry water from one of the rings in the shaft to the lower level. The rings are boxes around the sides of the shaft which catch the water coming out of the rock, slate or coal, and are put in to prevent the water from falling down and making a regular shower bath of the shaft. At the ring in question a large spring in the slate, about 30 feet below the primrose vein, had been struck, the water from which is apparently as pure as crystal.

Some four months since it was found that this wooden pipe had become so clogged with the reddish brown sediment that is deposited by all mine water, that the open space in it was not more than two inches in diameter, and not large enough to carry off the water from the ring. Consequently a new pipe was put in, and the old one, nearly closed with the sediment adhering to its sides, was left standing. The water was then turned into the new pipe, and cut off from the old one, which is some 50 feet or over in length. On Friday last, after remaining in the shaft without any water passing through it for over four months, the greater part of this old pipe was taken out, and when broken open the wonderful phenomenon presented itself that this sediment was gradually changing into what appeared to be anthracite coal. About half an inch of the inside of the sediment lining the pipe had changed into coal, and the remainder was also gradually changing, the only portions of the sediment remaining quite soft, being that part deposited first and next the sides of the pipe. A cross section of the pipe now shows, commencing at the center, first a circle of about half an inch in diameter surrounding the two-inch opening remaining in the pipe, then a circle of sediment partly turned into coal, and then the sediment in its natural state and the sides of the pipe. The surface of sediment which was exposed to the action of the atmosphere has changed first, and the influence or chemical combinations which had changed its nature were gradually operating on the rest of the sediment. The process of formation is plainly seen in the sediment next that already turned into coal.

Samples of coal taken from the pipe have been tried on the blacksmith fire at the colliery, and it makes an exceedingly hot fire, but being of a softer nature than the natural anthracite, it clinkers badly. Fortunately there are any quantity of samples of this wonderful formation, and those who are unwilling to believe without themselves seeing and touching, can be accommodated.

Glacial Action.

At the last meeting of the English geological society, Prof. A. Favre read a paper on the old glaciers of the northern slope of the Swiss Alps, illustrating his remarks by a map on a scale of 1-250,000, showing the space occupied by the old Swiss glaciers at the time of their greatest extension, and founded in part upon evidence obtained since 1867, when he, in conjunction with Prof. Studer and M. L Siret, issued an "appel aux Suisses" for the preservation of erratic blocks. He said that in existing glaciers two parts may be recognized—an upper one, the reservoir or feeding glacier, and a lower one, the flowing glacier. Applying this division to the old glaciers of the Rhone and Rhine, the flowing glacier which occupied the plain had a surface nearly equal to that of the feeding glacier which was situated in the mountains. By means of several tables, M. Favre showed the hight attained by these glaciers, their thickness, the slope of their upper surface, etc., at various points in the Alps, the Jura and Swabia, and deduced as the result of the comparison of these numbers: first, that the Rhone glacier passed over several of the chains of the Jura, and that the ice covering these, far from being an obstacle to the extension of the glaciers of the Alps, actually reinforced them and served them as relays, the glaciers of the Jura having carried far on the Alpine erratic blocks; second, that the slopes of the upper surface were variable, and were null, or nearly so, over considerable spaces.

DO AMERICAN WORKMEN NEED FOREIGN TEACHERS.—We are so frequently reminded, says the Delaware *Tribune*, by transatlantic authorities, of our American deficiencies in thorough and systematic training, especially in the scientific and mechanical pursuits, that this item, recently brought to our notice, seems *apropos:* One of our Wilmington firms sent to Edinburgh a very finely constructed machine for grinding the calendar rolls used in paper mills. It was accompanied by explicit directions how it should be set up, one of which was that it must be set level. Word came back that it didn't work well, and an experienced man was sent over to see about the matter. He found that it had not been set level, and in consequence had already suffered injury and that, moreover, there was not a spirit level in Edinburgh equal to the American one which, fortunately, he had taken over, or suitable to set up a delicate piece of machinery. The imperfections in the level which had been used were the main reason why the machine had not been properly set. The American spirit level was a subject of great interest to the Scottish mechanics during its stay in their city, and so great was the fear of the establishment where it was being used, lest a rival concern might get hold of it, that they had it carefully locked up every night in their fire proof-safe.

The Mining Share Market.

As the Stock Boards have been closed during the holidays, of course there is little to report concerning mining stocks. The sssions held to-day, (Thursday), were void of animation, sales being few and prices low. Every one seemed to be "feeling" the market and a small businsse may be expected for the rest of the week. Our list of sales in another column will give the prices of last Friday and to-day. Mining and prospecting operations are being prosecuted with unabated vigor all along the whole length of the Comatock and throughout what is recognized as the silver belt. While all stocks are inactive, all is activity in the mines themselves. Although what is now being done, underground and on the surface, may produce no present effect, it will eventually tell in the stock market. We note that very few assessments were levied since our last issue, the mining companies having evidently even neglected this important feature while the office were celebrating the Centeunial.

The Color of Minerals.

The light of the sun possesses many remarkable peculiarities. It falls on the clouds, and being reflected from them they become visible. In falling upon terrestrial objects it undergoes many peculiar changes, and when reflected from certain polished surfaces it displays various brilliant colors. The action of light upon minerals is a very interesting study and greatly aids the mineralogist in determining the nature of the substance in hand.

Some minerals reflect the light thrown on them while others absorb it. The colors of minerals originate, as in other bodies, by a portion of the rays being absorbed while those that denote the color of the mineral are reflected. Some minerals are colorless; that is, the rays pass directly through them without refraction. This is the case only when such minerals are perfectly pure, according to the essential character of their chemical combinations. When they contain impurities they assume different colors, according as these colors are more or less absorbed or as they reflect the rays of light. Rock crystal, which, when pure, consists of silica alone, is colorless, but it becomes yellow, red, brown or black by a very small admixture of iron or magnesium.

Some minerals exhibit one color only; others a great variety of color. Fluor spar excels all others in this respect, being found red, enameled green, blue, brown, yellow and white. There are also minerals which display a variety of colors in the same specimen, of which metaciunaharite may be cited as a marked instance. The luster of minerals is a consequence of the various reflection of the rays of light which fall upon their surfaces. This luster, for convenience of observation and description, is graded into virteous metallic pearl wax and oily luster.

General News Items.

THE Olema hotel was burned up on the 29th ult.

AN oil excitement is engaging the attention of the Los Angeles people.

THEBE were very few fires in San Francisco during the celebration.

THE Chinese question in Congress may be regarded as in abeyance until next session.

THE Grand Army of the Republic, 5,000 strong, paraded in Philadelphia on the 3d.

CHILE contemplates the issue of an additional $3,000,000 in bonds. The measure is unpopular.

THE largest streamer in the State was displayed from the flagstaff in Portsmouth square. The flag is 125 feet long.

A MADRID telegram represents that the Spanish Government has determined to resist the claim of foreign residents in Cuba to exemption from war taxes.

THE House Private Land Committee have voted to recommend the passage of a hill appropriating $450,000 for the relief of General John A. Sutter.

THE Auckland *Star* of June 3d says that the Government favors the proposal of a cable via San Francisco, over the route surveyed by the *Tuscarora*.

SARGENT and Page have withdrawn their application for the consolidation of the Visalia and Independence land offices and the joint removal to Bakersfield. They will therefore be continued as at present.

SERVIA has notified the powers that unless they declare the Danube neutral and prevent the Turks from using it, Servia will obstruct it with torpedoes. It is stated that Prince Milan has arrived at Alexinatz. Servia has suspended the foreign telegraphic service.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertieements in the Mining and Scientific Press and other S. F. Journals.]

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

O'Harra Furnace.—Alpine *Chronicle*, June 24: Manager Chalmers, of the Exchequer mine and mill, has perfected his arrangements for the erection of an O'Harra Champion furnace at the Exchequer mill, and Mr. O'Harra will arrive here next week with a corps of men to commence work. With the completion of this furnace we look for the inauguration of better times in Alpine.

AMADOR.

Plymouth Rock Mine.—Amador *Ledger*, July 1: John Evans and Philip Kehres, the owners of this mine, which we incorrectly styled the Centennial mine in our last issue, write to us as follows: "The shaft is down 90 feet, and the bottom looks prosperous. The casing of the ledge is mixed up with decomposed quartz, iron and black sand, the gouge being a kind of whitish hine. The ground is soft and sinking consequently easy, and no trouble is experienced from water. Appearances are favorable for a permanent mine. The banging and foot walls are soft, but not heavy. The claim is favorably located for the running of a tunnel to strike the ledge at a considerable depth. A good mill site is close by, and water may be obtained at small cost all the year round. The last prospect that we made was from a hole drilled about 18 inches into the ledge, which yielded 25 cents. The shaft is well timbered, and a whim has recently been put up." The owners are poor men, but are anxious to prosecute work on the claim. They would be glad to dispose of an interest in the property, so as to secure the means to continue its development.

Hubbardville Mine.—Preparations are being pushed ahead in connection with this mine. A boarding house is in course of erection close to the works. Some time must elapse before the preliminary work is through with and actual mining commences. The operations are under the superintendance of Mr. Tregloan, an efficient miner, who will soon place the property on a paying basis if it is possible to do so.

Damming the Blue Lakes.—Amador *Dispatch*, July 1: The Amador canal company are preparing to construct a dam across the Blue lakes in Alpina county, for the purpose of supplying their ditch with an additional amount of water during the dry season.

BUTTE.

Gravel Mining.—Oroville *Mercury*, June 30: We met J. McSmith the other day, just down from his claim at the head waters of Big Timshew. He reports everything as looking in the best possible condition for a good run this season. He has a 70-foot bank of gravel before him, and plenty of water to work it with. The ground is rich, and he expects good returns from it when he washes up.

CALAVERAS.

Gravel Mining Jots.—Calaveras *Chronicle*, July 1: In Veith's hydraulic piping continues with unabated energy, the employment of powder in blasting the bank greatly forwarding operations. An immense quantity of gravel is being washed daily and the prospects are that the next clean-up will be something to brag of. At Duryea's, in Chile gulch, work is going on actively. The necessary drifts having been run, a large force is at present employed "breasting out" gravel. A mill for crushing the dirt is to be speedily erected. Emerson's hydraulic in Happy valley is in full blast and everything working to a charm. Operations are conducted on a big scale and we think it will take a big pair of scales to weigh the dust extracted. Cook & Co., the Calaveras hydraulicists, are also "pressing things." They have piped away a large area of ground and are now preparing to make a Centennial clean-up. The Gopher, Red Hill, Bob Paul and other claims are being actively worked which results that will give the "boys" a handsome Fourth of July "stake."

Brady Mine.—We learn that the giant crusher at the Brady mine is now working satisfactorily, the difficulty in discharging the pulp, at first encountered, having been obviated. We are informed that the crusher, Cooper & Cowles' patent, is developing a grinding capacity of from a ton to a ton and a half per hour. If the mill will work that quantity of rock there is no question but that the mine will pay large dividends. Mr. James Brady, a practical miner, has been reinstated superintendent.

Gwin Mine.—Work is progressing steadily in the 1100-ft level of the Gwin mine. The ledge has widened out considerably, all good milling ore. The batteries are kept in constant operation, the yield of the mine continuing about the same as heretofore reported. Sinking the shaft an additional 100 feet is also progressing rapidly and will soon be completed. Machinery is being placed upon the "middle" shaft through which the mine is to be worked when it has been sunk to the necessary depth. Great activity is observable in all operations connected with the mine, and the results are altogether satisfactory.

New Mill.—Mr. James Duryea is preparing to erect a mill on his claim, in Chile gulch, for the purpose of crushing the gravel. The grading of the mill site is already completed, and it is expected to have the machinery on the ground this week. Mr. Duryea has purchased the Hepburn quartz mill at Railroad—a 10-stamp battery—and will have the machinery at work as soon as it can be hauled to his claim and set up. The mill is to be run with water power, the iron pipe necessary for conveying water for that purpose being already in position. Mr. Duryea is now working his claim by tunneling, instead of hydraulicing as formerly, and keeps a large force of hands constantly employed "breasting out" gravel. The dirt is hard to wash, however, being so tenacious that it will not yield up all the gold it contains without crushing. To remedy that difficulty Mr. Duryea is going to put the gravel under stamps, and we have no doubt but that the increased yield that will result will much more than repay the extra expense incurred.

West Point Mining Jots.—The water has been pumped out of the Mina Rica, and sinking the shaft commenced. The ledge in the Champion is showing fully two feet in width, composed of very rich rock. Our informant states that the ore will mill $200 per ton. Sinking continues at the Josephina. First grade ore is being obtained. Fields & Co. are taking good rock out of the old "Williams" mine.

EL DORADO.

About Completed.—El Doredo *Republican*, June 27: It is expected that the work of completing the gap in the big ditch between Plum creek and the South fork of the American will be consummated the last of this or first of next week, when 5,000 inches of water will continually flow to us.

Bide.—We saw some specimens, said to be the average ore, a few days since, from the Bine lead, Spanish Flat, owned by Varozza, Witmer & Schreder, that were very fine. It will work $60 to $70 per ton, we should say. They intend to haul 50 tons to the St. Lawrence mill, three miles distant, for crushing, during the summer, and accumulate sufficient ore to warrant them in building a first-class mill before another year passes. A tunnel has been run in 80 feet alongside of the ledge, and wherever the ledge has been tapped, good ore has been developed. They are now sinking upon the ledge at the end of the tunnel, where the rock mentioned is being taken out. The ledge where they are now at work is about two and a half feet wide.

INYO.

Coso District.—Coso *Mining News*, July 1: We paid a visit to the Defiance mine yesterday, and found the main incline being pushed with vigor. The hoisting works are doing splendidly. No ore is now being taken from vein No. 1, in consequence of the sinking of the main shaft, which will facilitate the extraction of the ore, and at a much reduced cost. From the incline shaft on No. 2, large quantities of fine carbonate ore are now being extracted. The vein here looks remarkably well. On the south drift, No. 2, 84 feet from main tunnel, an incline shaft is being sunk in solid ore, and is now down 30 ft, shewing very fine ore. Vein No. 3, drifting and stoping. The front vein of No. 3 shows a body of five feet of splendid galena ore, with rich chlorides—drift running north 25 feet and south 20 feet—solid ore all the way. Back vein of ledge No. 3, opened up for 40 feet in length and 25 feet in width, with six feet of high grade ore, carbonate and chloride. Between both strata, which really form vein No. 3, another body of fine ore was struck on the 28th, which no doubt will connect both veins. Large quantities of ore of the very highest grade are now being shipped from this vein to the furnaces. The outlook for the Defiance was never more favorable.

Lee District.—The Emigrant company are sinking on the Valentine ledge, the ore increasing in quantity and quality as they go down, dissolving smooth, straight walls, leaving no doubt as to the fissure character of the vein. The Cactus proves to be between 30 and 40 feet in width. The mill started up on the 27th ult., and has been running very smoothly. The first shipment of bullion will be made in a few days.

KERN.

Havilah Mines.—*Southern Californian*, June 29: Jenin, Hoffman and other San Francisco men, after spending a week examining the mines at Claravtie, have purchased them, and are moving the Kelso valley mill there, with a large gang of men, intending to devote a large outlay to the development of that section. The mines of Havilah are showing great improvement. The New World, which lies due west of town, has shown better prospects, and is likely to be put in a state of progress.

Mr. R. H. Stretch, who has taken the management of the Amoor, is making advancement which promises well, and encourages the dormant owners of adjacent mines. The Band Hill is attracting a good deal of attention. The lack of good miners is an impediment not easily overcome, but with the new discoveries there will be a return of the rush to that section, and the prediction is general that a great change is at hand.

NEVADA.

Rich Gravel.—*Foothill Tidings*, July 1: Very rich gravel has been struck in the prospect claim of Mr. Ragan, near Cement hill, in this county. Rumor has it that $6 to the pan was washed out. On the other side of the same hill the claims belonging to Scott and others are looking splendidly, and both are supposed to be on the old river channel.

Prospects Well.—Nevada *Transcript*, July 1: We learn that the mining claims located on Selby flat, superintended by John Cashin, and which have been opened this spring are being worked, and that the gravel prospects well, and everything looks favorable for the development of a good mine.

PLACER.

Opened Again.—Placer *Argus*, July 1: The old Caperton ditch, a branch of the Bear river ditch, starting at Newcastle and following the ridge for ten or twelve miles, has been put in a complete state of repair, and water will be turned in the early part of next week. This branch has been allowed to go down has not been in use for two or three years. The flumes have been replaced, the ditch cleaned out and and everything put in good shape. It will be kept up hereafter, and the country along the line is assured of a steady supply of water, something it has not enjoyed for some time.

Mining Items.—Dutch Flat *Forum*, June 29: We have nothing particularly interesting to offer this week, further than nearly all the claims in the district continue washing as constantly as the character of the gravel and circumstances will permit. The Pacific cleaned up yesterday and fully sustained its reputation of being the most profitable claim in the district. The Lakamp was cleaned up and is on again. The Boston is washing and is doing as good as could be expected under the circumstances. The Franklin is under a small cloud at present, owing to the misfortune of having the shaft plugged by a blast. It will, however, be but a temporary delay, and washing will soon be resumed with sufficient loose gravel in sight to keep the claim washing for some time to come. The Southern Cross is at present attracting considerable attention, from the fact that the incline which was being raised from the end of the tunnel has reached the surface of the gravel. Sluices will be immediately constructed in the tunnel below and washing commenced soon thereafter. The Polar Star continues washing and working. From the numerous reports we conclude that the claim either contains a great many boulders or the foreman is practicing for the Fourth of July. The Elmore Hill claim, with its rocky front, is being worked with unusual vigor. A blast of 60 kegs of powder was exploded on Friday evening last, crumbling the front of the bank in excellent style. The Yankee tunnel is being driven with vigor. During the week ending last Saturday evening, the drillers fired 11 face shots, advancing 43 feet. Considering that the rock is trap, and the face of the tunnel is 8x9 feet, this can really be termed very fast. The Baker shaft is being sunk by one shift of men. It is the intention of the superintendent, however, to increase this force to three shifts on the first of the month, men for this purpose having already been engaged.

PLUMAS.

Mining Jots.—Plumas *National*, July 1: The tunnel now being run by the Bell company is progressing at the rate of 25 feet per week. Archer, formerly of Newtown, has an extensive mining operation in full blast at Long bar on the East branch. The claim is nicely fitted up, and Arch thinks he has got a deep channel through the bar which will pan out big when he gets bottom.

SAN LUIS OBISPO.

Quicksilver Mines.—San Benito *Advance*, July 1: In the Cholame valley the mines are nearly all idle at present through dissensions and lack of means. The California, Nevada, Avenal, Fords, Delalu and Bosina quicksilver mines present excellent prospects. Tunnels extend into all of them, and several shipments of metal have been made from the California and Nevada. The Bed Rock coal mine has the appearance of being a mountain of solid coal; the deeper it is penetrated the better is the quality. Samples of the black diamonds have been forwarded to this office for public inspection. We consider this coal equal to the Cumberland, and when placed together and compered, it is a difficult matter to distinguish the difference. There is a fortune in this mine as soon as a railway connection is secured. The mining developments of the whole district excite the wonder of old miners, who consider the prospect equal to any district on the coast. The principal metals known to exist in large quantities in the district are quicksilver, iron, antimony, menganese, gypsum and coal.

SONOMA.

Palham Mine.—*Russian River Flag*, June 29: The Palham mine is situated at Sausal creek, about one-half mile above the fork, and near the head of the canon. Last fall a Vallejo company sunk a shaft 60 feet, but during the winter it fell in. They commenced work again last spring, engaged Silas Peter to haul lumber and by this time they have the shaft clear, no doubt. Specimens from the lead of which they were in search assay rich in gold and silver.

Nevada.

WASHOE DISTRICT.

Con. Virginia.—Gold Hill *News*, June 29th: Daily yield, 350 tons of ore. The mine is looking well. The station at the 1500-ft level has been completed. On the 1400-ft level the drifts and winzes are being enlarged, so as to give a better passage for the air and cool the level. On the 1500 ft level a drift has been run west to tap the bottom of the shaft, and enable the extraction of ore from that portion of the mine. The east drift on the 1500-ft level has been connected with the west drift from the C. & C. shaft, and although the draft of air is not so strong as expected in the beginning, the benefits will soon be apparent in the steady cooling of the whole mine. The north drift on the 1700-ft level is steadily advancing, and taking into consideration the large size of the drift and the intense heat encountered, is making good progress. Sinking the C. & C. shaft is making the usual rapid rate of progress. The yield of bullion for June will not fall short of that of May, notwithstanding the loss of four days' time during the month. The erection of the new battery and amalgamating mill are each making rapid strides toward completion.

Sierra Nevada.—The north drift on the 1000-ft level of the new shaft is steadily advancing, the face still in soft ledge material. Sinking the winze below the 700-ft level of the old shaft to connect with the main south drift on the 1000-ft level is also making steady progress. Everything is and about the mine is in splendid working condition, and the developments at all points are being forwarded with all the dispatch possible.

Opher.—Daily yield, 350 tons of ore. The ore breasts both north and south on the 1800-ft level are showing finely and promise an excellent yield of good ore. The north drift on the 1600 ft level is steadily advancing toward the south line of the Mexican, the face in porphyry. The 1700 ft level is again in good working condition, and the prospecting in that portion of the mine can now be resumed in good earnest. Sinking the incline is being pressed with all possible force at three different points, and will now soon be completed down to the 1600-ft level. The mills are kept running up to their full crushing capacities, and the yield of bullion for June will exceed that of any month since the destruction of the hoisting works by fire.

Justice.—The ore stopes are looding from the third station down to the 600-ft level are opening out finely and promise a large yield of excellent ore. On the 600-ft level both the north and south drifts are steadily advancing, the face of each in very favorable quartz. The yield of bullion for June will not be far from $55,000. The company is now contracting for a lease of the Pioneer mill, which, if they obtain it, will give them a crushing capacity sufficient to much more than pay the running expenses of the mine.

California.—Daily yield, 500 tons of ore. The ore breasts on the 1500-ft level are looking splendidly and are yielding rich ore. The ore breasts are also being opened on the 1350 ft level preparatory to extracting ore. The east and west cross-cuts on the 1600-ft level are still in rich ore, and that level is giving promise of a richer, better yield of ore than either of the levels above; in fact the more the mine is opened the richer and better it shows. On the 1400-ft level two crosscuts are being run to cut and prospect the ledge further to the northward than it has yet been developed. The yield of bullion for June will exceed that for the month of May, and insures the payment of the regular monthly dividend of $2 per share.

Bullion.—No work was done during the week in the Alpha drift on the 2000-ft level until yesterday, on account of the rise of water in the 2030 ft station of the Imperial shaft. On account of lying still the drifts are still so hot that but slow speed can be made. The upraise from the 1700-ft level is hourly expected to connect with the winze below the 1400 ft level. When this so desirable result is attained, a ventilation of the 1700 ft level will be secured, and the working of the mine to that depth can be commenced in good earnest.

Julia.—The south drift on the 1300 ft level is opening up with every prospect of a valuable ore development not very far ahead. The ledge is much more solidified, and the quartz and ore of a more concentrated character than it has been heretofore, on either of the levels above. On the 600-ft level the face of the west drift has penetrated the hard belt of rock encountered and again pessed into soft ledge material of a very encouraging description.

Calcutta.—This is a new mine in American Flat district, a little to the south and west of the Rock Island, recently located by parties in San Francisco. E. W. Worsham, President of the company, arrived here last week, and started men to work immediately grading a road to the mine. The company intend boring to a depth of 500 or 600 feet, and feel confident of striking a rich body of ore at that depth. The machinery, boiler, diamond drills, etc., are being hauled to the mine to-day, and the work will at once be prosecuted with all vigor to a depth of 600 feet.

Gould & Curry.—Enlarging and repairing the main shaft is making excellent progress. The new pumps for the stations in the shaft have arrived, and nearly all of the other machinery is now on the ground. The machinery for driving the large fan at the mouth of the old lower tunnel is finished. The fan is something entirely new in this section, and its operations for a while will be noted with much interest by the mining men of the Comstock.

Imperial.—The stoppage of the pumps on the 2000-ft station, and the consequent rise of water in the station and in the drift has prevented much being done in either the drifts or north winze on the 2000-ft level during the week.

Belcher.—Daily yield, 400 tons of ore. The ore breasts are looking well and showing little or no change. Sinking the main incline is going steadily forward.

Phil Sheridan.—Sinking the shaft is making steady progress, the bottom still in very favorable ground. A considerable pocket of water was struck during the first part of the week, but the flow is now rapidly subsiding.

Chollar-Potosi.—Daily yield, 120 tons of ore, the average assay value of which is $31 per ton. Sinking the main incline is going ahead at the rate of two and a half feet per day. The rock in the bottom is quite hard.

Ward.—Sinking the shaft is making splendid progress. It was sunk and timbered in the best of style during the past week a distance of 35 feet, and is now down a distance of 250 feet in depth. The erection of the new hoisting works is steadily progressing.

West Belcher.—The heat has been so great in the drifts for the past week that but slow progress could be made. The erection of a large blower will, however, greatly benefit the circulation in a day or two more.

Daney.—The shaft is now down 517 feet. The heavy flow of water is gradually decreasing, and the pump is now handling it with the most perfect ease.

Utah.—Sinking the main shaft is going rapidly ahead, notwithstanding the extreme hardness of the rock in the bottom. The flow of water from the bottom of the shaft is steadily decreasing.

Yellow Jacket.—Sinking the east winze in cross-cut No. 3 is making fair headway. It is now down about 80 feet, the formation penetrated showing little or no change.

Savage.—The erection of the new machinery is getting well advanced, and will probably be ready to start up by the 20th of July next.

Alta.—The foundations for the huge pumping machinery have been completed, and the sole plates laid ready for the reception of the engine and other heavy machinery.

Kossuth.—The main south drift on the 350-ft level is in quartz and ore of a very encouraging character.

Bock Island.—The flow of water is still strong from the west drift on the 850-ft level. The pumps are kept running up to their full working capacity. The flow of water has the appearance of being gradually on the decrease.

Best & Belcher.—Everything waiting on the repairs to the Gould & Curry shaft, and the starting up of the new pumping machinery.

Baltimore and American Flat.—Sinking the main incline is going ahead rapidly, the bottom in good sinking ground.

Silver Hill.—The flow of water is now easily handled by the pumps.

Overman.—Daily yield of ore, 30 tons. Sinking the main shaft is making good progress.

Twin Peaks.—The fine ore developments in the ledge found at the 75-ft level being fully satisfactory and such as to warrant the expenditure of any amount of capital in its practical working, work is suspended at this point and only confined to keeping the water ont. Grading for a first-class new working shaft of three compartments is now commenced 300 feet further east. This shaft will intersect the ledge between 300 and 400 feet below the surface and work it to any depth.

Hale & Norcross.—The coping stones are being placed on the foundations for the new machinery, ready to receive the sole plates of the engine. The engine, and in fact almost all of the machinery, is on the ground ready for erection.

Mexican.—The connection of the north winze in the Ophir ground with the north drift on the 1600-ft level has greatly benefited the ventilation in the Mexican, and enables the miners to make much better progress with the work at all points.

North Con. Virginia.—Cutting out for the boh pits and pump stations in the shaft is making excellent progress. The erection of the heavy stone foundations for the new machinery is making steady headway. A large portion of the new machinery is already on the ground ready for erection.

Dayton.—Sinking the the main shaft is making splendid progress. Driving the prospecting drifts on both the 500 and 700-ft levels is going steadily forward. A day or two since a strong flow of water was encountered in the north drift on the 700-ft level, which run the pump up to ten strokes per minute, but fatied to give any serious trouble, as the pump worked with as perfect ease at that rate as at less.

Succor.—Finding the old pumping machinery totally inefficient to drain the heavy flow of water at the bottom of the shaft, all work has been stopped in the shaft and much larger and more powerful pumping and hoisting machinery has been contracted for. The grading and excavations necessary for the foundations for the new machinery is now being made ready for its erection as soon as it arrives on the ground.

Crown Point.—Sinking the main incline is being pushed vigorously downward, the bottom in very hard rock. The main south drift on the 1700-ft level is steadily advancing, the face still in low grade ore. A steady but limited flow of water is coming in at the face of the drift.

Lady Washington.—Some little delay has been experienced owing to the non-arrival of the plunger pump machinery, but that has arrived, is in position, the connections are being made, and the whole will ha started up and sinking recommenced about the Fourth.

North Carson.—The new works are now in full and successful operation, and the machinery works smoothly and well.

Superior.—Sinking the shaft is being energetically prosecuted as usual, but no increase of water to interfere, and ground working favorably.

Mint.—The main shaft is now down 1,140 feet. The flow of water is still light

Vivian.—The ore breasts both north and south on the tunnel level are showing well, and are yielding the usual amount of good milling ore. The water in the incline is gradually decreasing.

Tahoa.—Sinking the new shaft is making steady and favorable progress.

Cosmopolitan.—Face of main tunnel or adit north still in good milling ore. The fine ventilation given by the upraise to the surface is of great advantage in the working of the mine.

Monumental.—Sinking the shaft is going steadily ahead; the only trouble encountered is having to hoist the rock so great a distance by hand. The shaft is now down 193 feet.

Pictou.—Streaks and bunches of quartz continue to be met with, giving good assays.

Hazon Con.—Sinking the combination shaft is making steady headway, the rock in the bottom blasting out finely.

Union Con.—The face of the north drift on the 1300-ft level is still in quartz and ledge matter.

Caledonia.—The water is reduced in the shaft to within ten feet of the bottom.

Flagala.—Both drifts are making good progress. Quartz in face of west drift showing better, with small streaks of ore coming in.

Lady Bazan.—Work on the pits and foundations for the new machinery is going steadily forward.

Prospect.—Total depth of shaft, 358 feet. Bottom in hard but good working porphyry.

South Con. Virginia.—Expect to have good ore developments to report before long.

Nevada.—Face of drift still in low grade ore, some streaks of which give high assays.

Baltic Con.—Drift pushing ahead, with good working material in the face.

Montana.

Items.—Butte *Miner*, June 17: On the Ohio mine Messrs. Thompson, Venner & Co., continue to hoist about two tons per day or $500 to $700 ore. This mine is about two miles north of Butte, and promises to be one of the best in the camp. The Howe mill continues to pound away on Burlington ore. The former run on this ore yielded $104 per ton, which was an average of the ore. We will give an extended notice of this mine at an early day. At the Banker lead, which mine has been worked for some time past, taking out rock running from $50 to $150, there has been discovered a rich streak of quartz which assays from $300 to $350. This is a fortunate strike at the present time, as the Banker is a comperatively free milling ore, just such as the mills here with furnaces incomplete for roasting stand most in need of. A ready market can at once be found for all high grade ores of this character. Yesterday, at the La Plata mine, while engaged in sinking upon the main shaft, a heavy charge of powder was exploded with a result not expected, for, instead of knocking the bottom out of the mine, it came near raising the top off, destroying the railroad track and somewhat injuring the shaft house. With the present force engaged at work, Messrs. Downs, Larry & Co. expect to lower the shaft at the rate of four feet per week, so that by fall they will put in eight many additional hundred tons of ore.

Utah.

Bingham.—Cor. Salt Lake *Tribune*, June 21: The old Telegraph rattles away on that inexhaustible ore body with a force of 80 men. The ore house on the tramway is now fixed so that seven cars can be loaded at one time. The Grecian Bend works 25 or 30 men on ore, and Brother Bartlett is still at the helm. A rich strike has been made in the Hamlin, since which time—three days—two of the boys took out 20 tons, and are now delving away on a three foot breast of first-class ore. The owners of the Hamlin are in a fair way to see Philadelphia.

Rush Valley.—Mining matters have decidedly improved throughout this district the past two weeks. Quite a town has sprung up at La Ronville, surrounding the Southport mine. Lawson and Shull are pushing everything in and around their mine, and making all improvements of the most substantial kind. The quick and energetic development of the Southport mine, with its grand yield of much sought-after ores, has stirred miners and prospectors into renewed activity and exertion. Many mines and prospects that have lain idle for years will, within a few weeks, be contributing ores to swell the bullion production of Utah.

(Continued from Page 26.)

cylinder in three and a half hours! He also shows a riveter which has a hydraulic pressure accumulator that will give a pressure of 6,000 pounds to the square inch. Not much chance for a rivet to escape being jammed well down under such a pressure! Nearly all the iron work in the main exhibition building was riveted by these machines.

Machine Tool Making in England and America.

Machine tool making, as a distinct branch of industry, is of quite recent origin. Mechinists formerly made, each for himself, such mechines as they needed in their shops. The result of such practice was very imperfect tools, and still more imperfect work was obtained from them. Mr. Joseph Whitworth, of England, has done much to secure precision in tool making, a condition which the delicate and intricate state of manufacture now demands; and especially the practice recently introduced into this country of manufacturing machines and implements by "assembling," or meking all the parts of a machine interchangeable with others of the same class and size, as in Colt's pistols, American watches, sewing machines, etc. We believe Mr. Whitworth was the first to urge upon machinists throughout the world the adoption of certain conventional standards which have now come into general use. As early as 1848 Bancroft & Sellers, now Wm. Sellers & Co., commenced the manufacture of machine tools, and from that time to this that firm has kept at the head of the business, both in regard to perfection of manufacture and extent of business carried on. As an evidence of the perfection which Mr. Sellers has attained in his manufacture, he shows here a machine for the production of true surfaces, so accurate in its work that two straight edges of steel, when finished by it and pressed together perfectly clean and dry, will adhere so closely as to require considerable force to separate them. A special piece of work of this kind was recently executed in England by Mr. Whitworth, which was heralded all over the world as a most remarkable triumph of the precision to which that eminent mechanic had arrived in finishing off his work. Mr. Sellers does this every day, and the fact would scarcely have been thought worthy of record, had not your correspondent in seeing it been reminded of the publication in regard to Mr. Whitworth, and which was noticed some three or four months since in the Mechanical Progress department of the SCIENTIFIC PRESS.

The introduction of American tools into the English market, as above alluded to, and American ideas into English shops, is a very significant fact, and worthy of a prominent niche in the records of our first hundred years of mechanical progress. Our English cousins have become convinced that, in order to hold their place in the mechanical world, they must copy after the Americans in a more general substitution of tools for head labor, as being both cheaper and more precise. Fortunately for them, the advanced intelligence of the age is fast driving away with the opposition of the English laborer to the introduction of labor saving appliances, and the question is beginning to be asked now, "Where shall we get our tools?" Such exhibitions as the one now in progress furnish the answer. No such exhibition of machinery as is here shown would be possible in Europe—from those to the manor born. Many of the machines have no existance there, while those that they have are used but sparsely on account of the opposition of workmen to their more general introduction, which still prevails. The general spread of knowledge and liberal ideas, greatly aided by district, national and international fairs, are working important revolutions, which will continue to go forward and tell largely upon the world's progress during the next hundred years. We of the present generation cannot witness the results, but our children's children will, and may we not hope—have we not good reason to believe—that such progress will be equally as fruitful in results as those we see before us to-day, as the result of the last hundred years. W. B. E.

Botanical Excursions.

[By J. G. LEMMON.]

No. 3.—The Big Trees Revisited—Criticisms and Consequences.

"Mail! Webber lake mail!"

The trapper's voice was never more welcome.

"Come down, come in," I cried, flying to the door and throwing it wide open.

Leaving his snowshoes up on the high white plateau, he descended by the ice-floored steps cut in the snow to the porch, and tossed a large package of letters and papers into the room.

To the devotee of a science whose better prosecution often requires months of secluded study amidst out-spread subjects, scarcely a visitor is endurable save the mail carrier.

While eagerly discussing the local news with the weary mountaineer, I placed substantial food and a cup of hot coffee before him, then ate eagerly seated myself to devour my letters. Reserving those from the good Dr. Gray until the last, I tore away envelopes and reveled in a right royal feast. Messages of remembrance from soul kuit friends in the valley below, lisping of love from the left and lone, tokens of friendship from comrades on late excursions, careful inquiries from devotees of the amiable science of botany, propositions to exchange specimens from new and distant correspondents, warm congratulations from patrons who know of the long struggle and its glorious reward, messages of cheer from eminent and venerable scientists. Oh, the feast was a full requital for the long dearth which gave it zest. At last I reached the viands—the double-sheeted letter from Dr. Gray. His letters always thrill me with emotion. In brief, but plain terms, they reveal the warmest heart, the kindliest interest, the most helpful self-denial. Reverently I drew the sheets from the envelope and read, first, a report of my last flowers sent him. With quickened pulse I noted the new species found, and read the comments thereon and the names, conferring more honors upon assisting friends. Next came suggestions as to territory for further research, practical directions for gathering valuable seeds and plants, then congratulations upon past successes, hopes for the future, and envyings of my opportunity to roam the Sierra at will in summer, then to retire to Webber lake and study in winter, etc.

A length I reech the words, "I lately read your 'Scenes in the High Sierra.'" (My heart throbs violently at thought of the high compliment.) "They please and interest me." (Tumultous emotion, expressed by springing from my seat and capering around the room.) "They are racy and artistic." (Ecstatic delight! chairs, tables and libraries are surmounted, and I perch upon a high cabinet.) "But," he continues, "in your graphic description of the Big Trees, like California writers in general, you fall into a great error." (Heart stops with a pang!) "Over 3,000 years old!" he quotes. "Did you count the rings?" ("Fool that I did'nt!" I hiss, sliding down to the sofa.) "Did you ever see any one who did?" ("That lying report of Hittell's!" I gasp, jumping to the floor and stamping a figure of the carpet.) "It is only writing large after the fashion." ("Consternation!" I cry, sinking upon the sofa.) "That is an over-statement" ("Horrors!") "which I have been fighting" ("Zounds!") "for the last 25 years." (Speechless I roll upon the floor.)

* * * * * *

Going For the Facts.

The summer following, that is, in 1875, I took a trip of 400 miles to revisit the Big Trees, count their rings and bring away sprays, cones, seeds, bark and wood sections for the Centennial. I visited several groves, closely examined hundreds of trees, especially giving attention to the fallen and shattered monsters, generally larger than living trees of the same grove.

The great *Sequoias* are monsters indeed for size and magnificent in their colossal appearance; they are well worthy a trip across the continent to behold, but why exaggerate their age? The truth is strange enough. "Over-statement," Dr. Gray mildly puts it. It is, indeed, a wonderful deviation from the truth when to large figures we add double their sum. From this time forward I must help fight the "over-statement." The battle will be long and fierce, no doubt, for the story of 3,000 or 4,000 years is very prondly related and never fails to excite interest; and it is repeated in nearly every guide book for tourists, moreover reiterated by eminent travelers and close observers, including John Muir, than whom none gives us such charming views of mountain scenery, such picturesque forest studies. But let the truth always be told, searching for it, if need be, under the most deceptive appearances. I scold myself daily because, for want of time, I took the figures of reputed authorities and gave currency to the big story of the Big Trees. Let me retract so much of last year's "Scene II, The Big Trees" as was carelessly based upon their reported great age of 3,000 or 4,000 years, and substitute the following cold facts and estimates. I substitute the true figures cheerfully, gladly, triumphantly. The big trees are but 1,200 to 1,500 years old, and I am glad they are not older. There is proud satisfaction in the thought, but let me repress my joy and its reason for the present and proceed with the cool facts.

At the Big Trees.

On the 1st of September, 1875, I arrived at the famous Mammoth Grove of Big Trees in Calaveras county, and at once commenced careful observations.

First, a quiet, reverential walk among the tall fluted columns, my spirit dumb with wonder, my mind raised to sublime conceptions, my reason almost persuaded that any large story of the great *Sequoias* must be true. Round and round, in and out among the vast trunks the well-worn path leads. Here and there a long flight of steps enables the visitor to reach the upper side of the fallen trunks, where a most impressive view and delightful promenade may be enjoyed. Marble slabs imbedded in the soft bark, high up on each tree, bear its name and generally the initials of the namer. Near the road, almost the first to greet the visitor approaching from the north, stands a group of noble trees bearing the names of Henry W. Longfellow, Prof. John Dana, Dr. John Torrey and Prof. Asa Gray. During this first half-day of silent gazing, I found myself frequently returning to this group of scientists with a sublime poet added, and trying to commune with the master spirits they commemorate. During my last call a cone from the lofty crown of "Prof. Asa Gray" fell at my feet; eagerly I seized it and wrapped it in paper; another and another followed. The squirrels were harvesting, so the seed must be ripe. I drew my army revolver and fired a round of six cartridges up into the crown, rewarded by the fall of a limb bearing a dozen cones. As I bore away the beautiful little cones with their tiny, parsnip-like seeds, I thought how much this precious fruit symbolizes those richer fruits which that other Professor Gray showers upon all who but ask his bounty. Hard at work in the great herbarium at the Cambridge university, he is devoting, perhaps, the last herculean energies of a life filled with toil to the completion of our California Botany. Receiving no salary while on this extra work, and hiring assistants in special fields, he toils almost incessantly, ever the master mind to direct research, ever the umpire to decide knotty points, yet ever the kind patron, ready to turn aside, examine the plants of the young collector and help the humblest applicant for knowledge.

Then the good doctor's tenacity for truth is so strong! No big stories for him, no flights of fancy, no careless writing! I think of this with bated breath, compressed lips, clenched hands and firm tread as I prepare for work in earnest on the morrow.

Age of the Big Tree Stump.

The stump of the very large tree which was bored off with pump augers in 1852 to form the floor of a house, affords a fine opportunity for counting, since it is so evenly smoothed off, but still more time is necessary to do it accurately than most observers allow themselves. This tree should certainly be considered a fair sample of the oldest of the present generation, for it is one of the largest ever seen. Its circuit at base is 97 feet by my tape line, held at one end by a Puritan and master builder from Boston. Longest diameter without bark, five feet above the base, 24 feet 10 inches. Shortest diameter, 22 feet eight inches. The bark averages 18 inches in thickness, making the entire longest diameter of the tree at five feet above base, over 27 feet. A few other trees are met with measuring as much or more at base, but they are generally swollen outward and hollow like the shaft of a light house. This monster tree was as straight and sound as a candle, hence it was undoubtedly the largest perfect tree ever yet seen.

I spent nearly a day counting the rings of this stump, and of the butt cut of the tree lying near it. I counted carefully both ways, putting in pins to mark the place of hundreds. The stump being a little irregular in consequence of its near roots, I counted in three places along three equidistant rays. The first count was 1,260 rings, the second count was 1,258 rings and the third count was 1,261 rings—average age, 1,260 years. Counting on the butt, cut 24 feet from the base, the rings were of course a few less, 1,242 in number, but all very plainly discernible, and presenting exact uniformity in their decrease in thickness from heart to bark. I availed of this uniformity of decrease by establishing, after many counts of different trees, a rule for determining the mean number of rings to the linear foot, and fixing the locality on a cut across these trees where the rings are of average thickness. That point is just one-third of the distance from the bark to the heart. At the heart the grains are often three-eighths of an inch thick, at the bark as thin as paper. The average, as determined by countings of all the logs in the grove which have been cut across, some half dozen or more, clearly established the rule that the rings of average width are found one-third of the way from the bark to the heart. This rule proved very useful afterward in estimating age of broken trunks.

Age of "Hercules."

This monstrous tree was leveled to the earth by a gale in 1862. His body has been repeatedly cut across by an ingenious device, and the timber manufactured into relics and carried away. He was 285 feet high, and now measures 14 feet in diameter 25 feet from his roots. A careful count of his rings showed only 1,232 years. Eighty-eight of these rings, the average number to the half foot, just covered the space of half a foot at the distance of two and one third feet from the bark, which is one-third the way to the heart, as seen above. This tree is often reported as over 3,000 years old.

Leviathan,

Another prostrate monster, is about the same size, being 270 feet long, and 14 in diameter, but his body is not cut across or so broken as to reveal his rings.

The Father of the Forest.

Armed with the rule, derived as above stated, on the third day I approached the shattered trunk of this famous tree, fabled to have sprung from the earth soon after the deluge of Noah, over 4,000 years ago.

This huge patriarch has been shamefully overrated every way—his size given at 40 feet in diameter and his length at 450 feet. Exact measurement shows the diameter as only 18 feet at a distance of six feet from his roots, and his length about 300 feet. His trunk is broken or burned out in places, thus exposing cross sections where the rings of annual growth may be examined. With a hatchet and sharp knife I smoothed spaces of wood in three places, widely removed from each other along the trunk, but each one-third of the distance between the bark and heart, and thereon counted one foot of rings, with the result following: First count, 66 feet from roots, 232 rings; second count, 186 feet from roots, 254 rings; third count, 210 feet from roots, 276 rings. The diameter of the tree at each place must be considered, and is as follows: First place of counting, 12 feet; second place, 11 feet, and the third, 10 feet. Now the estimated whole number of rings (age), at each place is obtained by calculating, viz:

232x6,	semi-diameter at 1st place.....	1,392 Rings
254x5½,	" " 2d "	1,342 "
276x5,	" " 3d "	1,380 "

Adding these products and dividing by the number of counts, the average of rings (age), is 1,371⅓ years only. Probable full age at base, 1,500 years.

One oft-repeated story is true, however; that of a passage through a part of his body large enough to admit horsemen. This passage burnt out of his heart commences at a point 66 feet from the roots and extends 120 feet, coming out where was once a knot-hole, now enlarged by relic seekers to a wide doorway. I saw several ladies ride horses of medium size through this wooden tunnel, and one day while passing, riding one of my horses and leading the other packed with bulky specimens, I turned into the cavity and rode safely through. The ceiling overhead is four to six feet thick, so the grand promenade for visitors above is perfectly safe.

South Park Grove.

This grove contains about 500 trees, some of them of the largest class. One, the home of "Trapper Smith," is a vast swollen trunk at base, 90 feet in circuit and 30 in diameter. The "Livery Stable," which has received 22 horses at a time into its hollowed base, is 84 feet in circuit, and the "Primitive Church" is 81 feet. A fallen tree is 15 feet in diameter 20 feet from the roots. A cavity is burnt in it sufficient to comfortably shelter 25 or 30 horses, or to afford the passage of a Concord coach and its four-horse team for over 200 feet. Another, near "Trapper Smith's Cabin," and used by the tourists as a temporary shelter for their horses, is 16 feet in diameter and hollowed for a long way. These are certainly fair samples of the largest *Sequoias* both living and fallen, and the dimensions above given do not materially differ from some published statements, but counts and estimates of their rings reveal only 1,200 to 1,500 in number.

Other groves visited afforded exactly corroborative evidence, that though the dimensions, being easily determined, are often given accurately, the age has been generally grossly exaggerated.

As late as February last the writer saw a specimen of *Sequoia* in the Central Pacific railroad collection at San Francisco for the Centennial exhibition, which was sent from the Calaveras Mammoth Grove, and is marked "four thousand years old."

Triumphant Conclusions.

Now I firmly believe with Dr. Gray that this is an "over-statement," and, as I said, I am glad that it is such. Let India with her banian tree—which by the way is a mass of trunks, not a single one—take the palm for growth of 4,000 years, let African baobab trees reach back still nearer to the Garden of Eden, let Palestine boast of her cedars of Lebanon growing since Moses' time, and let Australia present upon every exploration by the close observer trees of undeterminable ancient origin; all these trees of the old world almost, without exception, are slowgrowing, fine-grained, stunted, gnarled, decrepit, unsightly old relics of past ages—only interesting because of their great age.

The tamona baobab, *Adansonia digitata*, is the largest in circuit at base of any tree yet known, but it is only 70 to 80 feet high. The cedar of Lebanon, with annual layers, so fine that a lens is necessary to distinguish them, is similar in shape, the trunk an abruptly tapering spike.

Now all observers admit that the California Big Trees, with their vast straight-fluted columns, 200 to 300 feet high and their immense crowns of finely divided, evergreen branches, are the most symmetrical and magnificent in form, the tallest and actually the largest in dimensions of any yet known in all the world. How satisfying to the pride of a true American, to reflect upon the inference derived from this comparatively new fact—formerly a most unwelcome one to the thoughtless, insomuch that loyal Californians prove their loyalty by declaring their belief in the great age of the Big Trees; hence the warfare to which Dr. Gray refers, and the great but pardonable assistance given to the erring side by eminent writers through their praiseworthy love of country.

But science always searches for the truth. Sooner or later the facts will come to be believed and they are always best. And the truth, in this case so long repressed, is most welcome because it gives foundation for the most reasonable and enthusiastic loyalty. Why, these grand giant trees are mere vigorous saplings yet, only 1,200 to 1,500 years old! Ages hence full-grown trees may be seen 50 feet in diameter and 1,000 feet high, only limited by the proximity of brother trees and the depth of the valleys where found. We can't expect them to be so unneighborly as to choke their brothers to death, nor to rise above the leveling winds that sweep over the canons of the Sierra. So let the old world pride itself upon old things, old nations, old creeds, old arts, old customs, old monuments; we of America rejoice that this is a new, unfinished world, with young yet colossal vegetable growths, strange yet beautiful animal forms, modern yet matchless peoples, adolescent yet full-fruit-bearing institutions, unprecedented yet unimaginable destinies!

"For still the new transcends the old,
In deeds and wonders manifold."

Finishing Centennial Work—Adieus.

Dear reader, again adieu for a reason; my

other excursions for 1875 were short runs here and there for isolated plants, and a flying trip late in the season through these beautiful northern valleys again, just to collect the autumn flora and tree specimens for the Centennial. As the season advanced the labor increased, employing my utmost energies to secure and prepare a creditable set of specimens of all the Sierra plants known to me, including 25 or 30 collected lately for the first time.

In September I hastened up to the forests around Webber lake to get sections of trees; that district embracing nearly all the trees of the Sierra and some species rarely seen elsewhere. With a hired assistant I cut down representative trees, often very large ones,—the *Picea amabilis* was 30 feet in circuit,—and took out uniform sections exhibiting bark and all the layers of growth to the heart, also cross sections of saplings, young stocks with stubs of limbs, leading shoots of old trees, blossoming and bearing twigs, cones, acorns, etc., so that the visitor by examining a set of specimens of any species can readily get an idea of the tree. These tree sections filled six large boxes and weighed over a ton. Despatching them with much trouble through the mud of the late fall season, and prepaying freight charges, I then set to work upon the flowers collected during the entire season. There were thousands of them, making three wagon loads, and were scattered all through my bales of papers just as gathered.

To arrange them into families at least 500 large receptacles were necessary. Three weeks of hard, swift work provided beautiful and appropriate herbarium rooms, and three more placed the plants hurriedly but carefully in their respective pigeon-holes. Another week brought out a choice selection of representative plants, packed them into a large box and despatched them after the tree sections, but by express, prepaid, to Dr. Geo. Vasey, Botanist, Agricultural Department, Washington, to be exhibited at the Centennial. During the week following I wrote these "Botanical Excursions" for the PRESS, then started for southern California, to meet and work with Dr. Parry during the winter and spring season of this commemorative Centennial year.

Though my work performed in good faith for the love I bear my adopted State was most arduous and expensive, costing at common rates of wages and for coin paid out nearly $2,000, for which I received but $400 in currency, yet I have the satisfaction of knowing that California will have a fine set of her flora at the great exhibition, which Dr. Vasey declares "is very satisfactory, but causes me much regret that you had so much expense upon them."

Dear, patient reader, good-bye, until we meet at the Centennial—or *somewhere*. Perhaps only in the RURAL, but anywhere, always welcome.

A MECHANICAL HORSE.—A mechanical horse is being made at the National iron works, New Brunswick, N. J., which is quite a curiosity in its way, and is to be on exhibition at the Centennial. The life size model has been operated satisfactorily to all who have seen it. Every movement of the horse is as natural as life. It walks, and lo! each joint of the leg is put in its proper motion, while the neck and head bob in appropriate unison, and yet the simplest mechanism is used, being nothing more than a few pulleys and one or two belts, the latter corresponding with the tendons of the natural animals. There are also four steam men being manufactured at Munn's machine shop. These men are for exhibition at the Centennial.

QUICKSILVER MINES.—Sheriff Philbrook was in from Cinnabar last week and represents everything in that district in a most favorable light. In the lower level of the Altoona mine a more extensive deposit has been struck and it proves to be richer than any of those heretofore worked. At present they are running one bench of five retorts and producing 10 flasks of quicksilver daily. When the furnaces are erected and put to work this mine will yield close on 1,000 flasks per month. Mr. Philbrook further tells us that prospecting is being extensively carried on and that parties at work on the various locations are hopeful and happy, indications being very favorable.—*Trinity Journal.*

VENTILATING FABRICS.—A patent has been taken out in France by M. Loubier for the production of tissues for upholstery purposes, which, while they admit air, shall keep out insects, and, at the same time, be capable of decoration and ornamentation like other fabrics, and retain their suppleness. These new fabrics, intend especially for use in hot climates, are produced by employing yarns of unequal thickness, both in the warp and the weft, in such a manner that the coarser produce interstices among themselves, which give passage to air and light, while the finer bind the coarser together and supply the ornamentation of the tissue.

TURBINES.—In 1854, Emile Geyelin made a wheel at Saltillo, Mexico, which was a double turbine (that is, a turbine receiving water between two movable wheels on the same shaft, which counterbalanced each other, and avoided the necessity of resisting the thrust from the head of water), for 160 feet fall, producing 125 horse-power, and turning with a speed of 1,850 revolutions per hour. This double turbine, though only 11 inches in diameter, propels a cotton mill of 10,000 spindles.—*Scientific American.*

GOOD HEALTH.

Care of the Hair.

A writer in *Harper's Bazar* says: To get and retain beautiful hair you must attend to daily brushing it, occasionally washing it, and periodically trimming it, and striving at all times to keep the general health up to the average.

Now as to brushing. The skin of the head, like that of every other part of the body, is constantly being renewed internally, and throwing off minute scales externally, and these are removed by means of the body brush. But it is not so easy to brush the hair as one might imagine. Few hair dressers, indeed, know very much about it. The proper time for the operation then, is in the morning, just after you have come out of your bath, provided you have not wetted your hair. Two kinds of brushes ought to be found on every lady's toilet table, a hard and a soft. The former is first to be used, and used well, but not too roughly; it removes all dust, and acts like a tonic on the roots of the hair, stimulating the whole capillary system to healthy action. Afterward use the soft brush—to give the gloss from which the morning sunshine will presently glint and gleam with a glory that no Macassar oil in the world could imitate. Whence this gloss? you ask. Why, from the sebaceous glands at the root of the hair, nature's own patent pomade, which the hard brush does not spread.

Secondly, one word on washing the hair. This is necessary occasionally, to thoroughly cleanse both head and hair. One or two precautions must be taken, however. Never use soap if you can avoid it; if you do, let it be the very mildest and unperfumed. Avoid so-called hair-cleansing fluids, and use rain water filtered.

The yolks of two new-laid eggs are much to be preferred to soap; they make a beautiful lather, and when the washing is finished, and the hair thoroughly rinsed in the purest rain water, you will find when dry that the gloss will not be destroyed, which an alkali never fails to do. The first water must not be very hot, only just warm, and the last perfectly cold. Dry with soft towels—but do not rub till the skin is tender—and afterward brush. Be always careful to have your brushes and combs perfectly clean and free from grease, and place other brushes on the table for friends of yours who happen to be Macassarites.

Pointing the hair regularly not only prevents it from splitting at the ends, but renders each individual hair more healthy and less attenuated—if I may apply the term to hair—and moreover, keeps up the growing process, which otherwise might be blunted or checked. Singeing the tips of the hair has also a beneficial effect.

It will be seen that I am no advocate for oils and pomades. My advice in all cases is to do without them if you possibly can, for by their clogging nature and overstimulating properties they often cause the hair to grow thin and fall off sooner than it otherwise would. Let well alone.

One word in conclusion, about dyes. Avoid them if you be your own friend. Hair dyeing is very satisfactory as far as dead hair is concerned, but on the living head its perfect success is a chemical impossibility. As to hair restorers, those that are not simply stainers, but depend upon the action of the light chemically altering and oxidizing the application after it has been used—their incautious use, I must add, is fraught with great danger.

A NATURAL DISINFECTANT.—Some interesting experiments were made very recently at Campbell's sewage works, Wandsworth road, London, with a new substance which is practically animal charcoal, and which will probably find extensive use at no distant date in purifying the effluent water of districts that treat their sewage by precipitation, in clarifying the waste water of dye works and mines, and the thousand and one other ways that will suggest themselves at once to persons conversant with sanitary matters. It is the product of a company that owns some 1,200 acres of the district on the Dorsetshire coast where the famous Kimmeridge shale deposit is found. This is a deposit which is of undoubted animal origin, and is supposed to consist of blubber, fish and other forms of marine animal life. However this may be, the shale is found to yield more plentifully than cannel coal, and at less expense, an excellent carbon, one ton of the shale, after giving off 9,000 cubic feet of gas, leaving 11.6 cwt. of residue, which is the sanitary carbon in question. This substance is found to have precisely the same properties and action for all sanitary purposes as animal charcoal that costs from £14 to £18 per ton, and the company hope to be able to produce it for one-fourth the price. The experiments adverted to, consisted in running sewage through a layer of the sanitary carbon, when the effluent water came out as clear as crystal. A more crucial trial still was made by mixing sewage with a compound of ink dye stuffs in solution, forming a liquid more intractable than would ever be met with in actual drainage operations; but the result was the same, the water running off perfectly clear, with no perceptible odor.

NECK VS. FEET AND WRISTS.—Every one must remark that a favorite article of winter clothing for children is a comforter swathed round the neck. This is a great error; the feet and the wrists are the proper members to keep warm; the face and throat will harden into healthy indifference to cold; but that muffler exchanged for an extra pair of thick socks or gloves would preserve a boy or girl really warm and well. Bronchitis and sore throat have declined fifty per cent. since the absurd use of high collars and twice round neckerchiefs went out of fashion; and if the poor would take better care of their children's feet half the infantile mortality would disappear. It only costs a trifle to put a piece of thick felt or cork into the bottom of a boot or shoe, and the difference is often considerable between that and a doctor's bill, with, perhaps, the undertaker's beside.

SMALL-POX SPREAD BY DOGS.—A rural sanitary organization in England has applied through Dr. Mackintosh (*British Medical Journal*), for an order from the magistrates to have all dogs in the district of Bolsover chained until small pox has disappeared in that locality. Dr. Mackintosh considers, and very properly, we think, "that the disease is spread from house to house more by domestic animals than by anything else." We believe that the more this subject is examined from this point of view the more the views advanced will be considered correct. It is possible also that the spread of other contagious diseases, such, for instance, as scarlet fever, may be explained in this way when all other recognized reasons have failed.—*Medical Record.*

HASTE IS NOT ALWAYS SPEED.—No two things differ more than hurry and dispatch. Hurry is the sign of a weak mind; dispatch of a strong one. A weak man in office, like a squirrel in a cage, is laboring perpetually, but to no purpose, and in constant motion without getting out of the spot; like a turnstile, he is in everybody's way, but stops nobody; he talks a great deal, but says very little; looks into everything, but sees into nothing; has a hundred irons in the fire, but very few of them are hot; and with those few that are, he only burns his fingers.

USEFUL INFORMATION.

Singular Property of the Leaves of the Tomato.

Dr. C. B. Bates has favored the Santa Barbara *Press* with the following translation from *El Mercurio*, a paper published in Valparaiso. It will doubtless be useful to many of our readers. I planted a peach orchard, writes M. Siroy, of the society of horticulture, and the trees grew well and strongly. They had just commenced to bud when they were invaded by the curculio (*pulgon*), which insects were followed, as frequently happens, by ants. Having cut some tomatoes, the idea occurred to me that, by placing some of the leaves around the trunks and branches of the peach trees, I might preserve them from the rays of the sun, which were very powerful. My surprise was great, upon the following day, to find the trees entirely free from their enemies, not one remaining, except here and there where a curled leaf prevented the tomato from exercising its influence. These leaves I carefully unrolled, placing upon them fresh ones from the vine, with the result of banishing the last insect and enabling the trees to grow with luxuriance. Wishing to carry still further my experiment, I steeped in water some fresh leaves of the tomato, and sprinkled with this infusion other plants, roses and oranges. In two days these were also free from the innumerable insects which covered them, and I felt sure that had I used the same means with my melon patch I should have met with the same result. I therefore deem it a duty I owe to the society of horticulture to make known this singular and useful property of the tomato leaves, which I discovered by the merest accident.

TO TAKE IMPRESSIONS OF LEAVES, ETC.—M. Bertot, of the Paris Academy of Science, has just made known a simple method of taking impressions of plants, requiring only a large sheet of paper, some olive (or other) oil, black lead, ashes and resin (or colophony). The paper is first lightly oiled on one side, then folded in four so that the oil may filter through the pores, and the plant may not come into direct contact with the liquid. The plant is placed between the leaves of the second folding, and in this condition pressed (through other paper) all over with the hand, so as to make a small quantity of oil adhere to its surface. Then it is taken out and placed carefully on white paper; another sheet is placed above (since two impressions can be taken), and the plant is pressed as before. On now removing it an invisible image remains on the paper. You sprinkle over this a quantity of black lead (or ashes, etc.), and distribute it in all directions, as in applying sand to writing; the image then appears in all its parts. With an assortment of colors, the natural colors of plants may be reproduced. To obtain fixity, resin is added to the black lead (previously) in equal quantity; the impression is fixed when it is exposed to a heat sufficient to melt the resin.

CEMENT FOR STONE.—The following recipe is asserted to produce a cement of a very superior character for uniting stone and resisting the action of water. It becomes as hard as stone, is unchangeable in the air, and resists the action of acids. It is made by mixing together 19 pounds of sulphur and 42 pounds of pulverized stoneware and glass. The mixture is exposed to gentle heat until the sulphur melts, when the mass is stirred until it has become thoroughly homogeneous, and is then run into molds and permitted to cool. When required for use it is heated to 248 deg. Fahr., at which temperature it melts, and may be employed in the usual manner. At 230 deg. Fahr. it becomes as hard as stone, and preserves its solidity in boiling water.

COLORING PROCESS FOR GEMS.—There is a factory in Idar, Germany, where the coloring of stones, for art purposes, is said to be carried on to a greater extent and more perfectly than in any other part of the world, the process pursued in thus converting chalcedonies and red and yellow cornelians into onyxes resulting in the production of admirable specimens, which are known and prized in all the markets of Europe and America. The peculiarity of this process consists in the fact that the ribbons or zones in the different varieties of chalcedony — which, in the kidney-formed masses of that substance, lie superimposed— differ in their texture and compactness; but owing to their similarity of color in the natural state they can only be distinguished from each other with difficulty. The stone is, however, capable of absorbing fluids in the direction of the strata; and as the strata possess this property in different degrees, it necessarily follows that if a colored fluid be absorbed, and the quantity taken up by the pores of the stone is different from every stratum of zone, a number of tints will be produced corresponding to the number of zones, each being distinct and colored in proportion to the quantity of the fluid absorbed. In this way a specimen of stone naturally but slightly colored may be rendered equal to fine stratified chalcedony or onyx, and may be employed equally well in the engraving of cameos, or for any other purpose where the variety of color can be rendered available.

AN ESCAPE FROM SCRUBBING FLOORS.—A lady writer, in one of her letters to the *Christian Weekly*, tells how she succeeded in obviating almost entirely the drudgery of scrubbing. She says she procured from a druggist three quarts of boiled linseed oil, and the same amount of shellac varnish. Also a paint brush. This quantity of material will cover as much floor as 40 yards of carpet, and costs only $3.50. The floors were cleaned as thoroughly as possible, and all spots that will not wash off ought to be planed off. We put on the first coat of oil in the evening, and the next morning it was dry. The following evening we put on a coat of the shellac varnish, which was dry by morning. Then after two or three days we put on the final coat of oil, but as the wood will absorb very little oil this time, we put it on with a flannel, and rubbed it in as thoroughly as possible. It was soon dry and ready for use. Now we have beautiful floors, easily kept clean by wiping off the dust with cold water. Once in three or six months we can go over them with a little of the boiled oil, and have them look as well as ever again. Such floors would rob "cleaning time" of half its terrors, and add largely to the purity of the atmosphere of our houses already poisoned by air-tight stoves and furnaces. It is a cheap reform and easily tried.

EXTERMINATING BEDBUGS.—Where all other means have failed to exterminate bedbugs, sulphurous acid gas has succeeded. Take everything out of the infested room, plug up all the windows tightly, close all chimneys, and empty about one ounce of powdered sulphur on a pan of hot coals, placed in the middle of the floor. Shut the doors and cover all cracks; let the sulphur burn as long as it will. Where the room is large, it is a good plan to fasten a piece of tin tube to the bottom of the pan, and to this connect enough small rubber pipe to lead out of the nearest door. By blowing into the end of the pipe with the bellows, the sulphur will be caused to burn more quickly by the draft created, and to give a denser smoke. After the sulphur has burned out, paint all the cracks in the floor and around the mop board with a strong solution of corrosive sublimate, and treat the furniture to the same before replacing it.

SCOTCH PIG BRANDS.—The letters "G. M. B.," used in connection with Scotch pig iron, indicate that they are "good merchantable brands." Of course there are also the special brands, which always sell at higher prices than the general bulk of iron known as "G. M. B.," and these include such brands as "Gartsherrie," "Coltness," "Langloan," "Shotts," "Summerlee," and "Glengarnock." At one time the "G. M. B." did not include the Ayrshire and East Country brands, as they were not deemed good enough to go into store as "warrants," but some of them have since been improved in quality, and have been also admitted into the "select society" of first quality special iron, which may be depended upon.

THE green outer husks of walnuts contain a yellow brown and remarkably fast dye, which is well suited for dyeing woolen or cotton materials, staining wood, etc. Wool thus dyed requires no mordant, is very soft to handle, and not like that died with vitriol. The shades of color obtained are from bright to dark brown. The husks may be simply kept dried till used, or placed moist in tubs, by which means their coloring power is further increased.

A good and simple furniture polish consists of a little Castile soap scraped into a pint of warm water. Add three tablespoonfuls of sweet oil; heat, and apply while hot.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 mos.	12 mos.
Per line..... .25	.80	$2.00	$5.00
Half inch (1 square)...$1.00	3.00	7.50	24.00
One inch..... 1.50	4.00	12.00	40.00

Four weeks are rated a month.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly se in solid type, giving in our columns one-third mor reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, July 8, 1876

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The New Mining Bill; The National Holidays; The Yellowstone Geysers, 32. Placer County Mines; A Small Quartz Mill; Primitive Stone Implements from Wyoming; Mineral Fields of New South Wales, 33. Patents and Inventions; The Tendency of Machine Manufactures; Book Notices, 36.

ILLUSTRATIONS.—Scenes in the Great National Park of the Yellowstone, 25. A Home-made Quartz Mill; Primitive Stone Implements from Wyoming, 33.

CORRESPONDENCE.—The Centennial at Philadelphia; Botanical Excursions, 26-30.

MECHANICAL PROGRESS.—New Rules of the English Patent Office; How the Bryant Vase was Manufactured; Curious Bursting of an Iron Tank; Air Casing for Steam Boilers; A Long Gas Pipe; Boiler Explosions; Danger of Passing Railroad Curves, 27.

SCIENTIFIC PROGRESS.—Perfumed Newspapers; Formation of Anthracite Coal; Glacial Action; Do American Workmen Need Foreign Teachers, 27.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 28.

MINING SUMMARY from various counties in California and Nevada. 29.

GOOD HEALTH.—Care of the Hair; A Natural Disinfectant, 31.

USEFUL INFORMATION.—Singular Property of the Leaves of the Tomato; To Take Impressions of Leaves, Etc.; Cement for Stone; Colored Process for Gems; An Escape from Scrubbing Floors; Exterminating Bedbugs; Scotch Pig Brands, 31.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 36 and other pages.

MISCELLANEOUS ARTICLES.—A Mechanical Horse; Quicksilver Mines; Ventilating Fabrics; Turbines, 31.

NEW ADVERTISEMENTS.

Method for Cleaning Copper Plates, M. H. Stowe, Pine View P. O., Va.; Manhat an Marble Company of California—Sale; Mariposa Land and Mining Company of California—Assessment.

A DISASTROUS REVERSE.—The sad news has been received from the Indian country, where Custer and his command were fighting the Indians, that the gallant general and his whole command were cut off and annihilated. General Custer with his two brothers, his nephew and brother-in law, seventeen commissioned officers and 300 regular troops, were all massacred by the fierce Sioux. The battle was fought on the 25th inst., 30 or 40 miles below the Little Horn. Custer attacked the Indian village of 2,500 to 3,000 warriors on one side, and Colonel Reno was to attack it on the other. Three companies were placed on a hill as a reserve. General Custer, officers and every man belonging to the five companies were killed. Reno retreated under the protection of the reserve. The whole number killed was 315. General Gibbons joined Reno. The Indians left the battle ground. It looked like a slaughter pen, as it really was, being in a narrow ravine. The dead were very much mutilated. This is all as yet known of one of the most terrible reverses that has befallen American arms in Indian warfare for many years. It is probable that the massacre will raise a feeling against the Indians more than that excited by the Modoc outrages, and that the Sioux will suffer for it to the end. The miners in that part of the country will have to leave until the difficulties are settled.

HALF A MILLION SACKS.—We are informed that Dr. Glenn, of Colusa county, laid in 500,000 sacks for this year's crop. It took two full boat loads to carry them up. The yield of the Glenn farm this year is estimated to be 30 bushels per acre.

The New Mining Bill.

We have not yet received the full text of the new amendment to the mining laws of the United States which passed the House last week. The brief telegram concerning it which has reached us, states that the bill provides that the annual expenditures on mining claims shall not be required until the patents are actually issued, but only after the application and final proofs of payment have been made. It also provides that in case an adverse claim is asserted and suit commenced after the filing of an application for patent, the annual expenditure shall not be required until the contest is determined by the courts. Page and Piper opposed the bill on the ground that the existing laws are working well, and that the amendments are unnecessary and tend to disturb the time for developing, that non-residents or speculators could hold claims without developing them by inducing other persons to assert bogus claims to the same land, and beat them in litigation indefinitely under this bill. Luttrell, Wigginton and McGinnis, of Montana, favored the bill, and it passed as recommended by the House Committee by a large majority.

There is evidently something wrong in the dispatch, or else this amendment totally changes the existing laws as far as they refer to annual expenditures on mining claims. According to the dispatch no further annual expenditures are required on claims which are not patented. It has always been understood that the clause requiring these annual expenditures was intended to make people work their claims and not let them lie idle, and also to compel miners to patent their ground, which they would do in order to get rid of the annual expenditure. If the telegraph has informed us correctly then we are to have no more annual expenditures except on claims which are patented, and henceforth there will be very few patented. It may be, however, that the sum required for annual expenditure will not have to be paid until a patent is issued and then must be paid in a lump; but this would not compel miners to do the work every year. In fact, the information so far received is so indefinite that we are unable to make any comments on the bill. As soon as we receive the full text of the bill we will publish it.

The National Holidays.

Dispatches from all parts of the State bring tidings of patriotic and spirited commemorations of the nation's birth. The local celebrations throughout the State were planned with unusual care and executed with unusual liberality. They were witnessed by large concourses and the Centencial spirit ran high.

Readers in distant parts will doubtless be interested to know some of the points of the three days' celebration in this city, and how the great things which we described in last week's PRESS were realized. Let us say first, in a general way, that the celebration was of such a grand and comprehensive character, awakening such general participation among all citizens, and was witnessed by such a concourse of the city's guests from all parts of the coast, that it will be always memorable. Never before has anything like it occurred; but so rapid is our growth and progress, one cannot tell how soon it may be surpassed in the future. If before the nation's second Centennial our State and city advance in the proportion they have during the last quarter of a century, what we shall call great to-day will be small indeed.

The Decorations.

As early as Friday before the Fourth, the city began to deck itself in Centennial livery. The stars and stripes were woven and interwoven into every conceivable shape and form. The beautiful red, white and blue colors tinged, edged, and crossed our somber city marts and business blocks until even the lower part of the city seemed crowned by a halo. Farther up, upon the hillsides, the decorations waved in graceful lines and shapes. The mansions of the wealthy were brilliant with gilt and colors, but many an humble habitation outstripped its proud neighbors in the fullness and grace of its patriotic drapery. During the day time the breeze was resonant with the flip and rustle of the flags, and at night the city was ablaze with colored light and fantastic lanterns. Some of the private and public decorations were notable, but we have no space to particularize. Suffice it to say that several streets were embowered with festoons of flags from roof to roof across the walks and carriage way. Arches were sprung across the streets bearing the national colors and the portraits of patriots. Large canvas sheets reproduced the scenes at revolutionary battles. Never before has the city shown such a bright attire. Everyone bought flags until the flag market was cornered, and even colored cambric increased its price six fold. We doubt not that a million dollars would be a low estimate of the amount of money expended for the one item of public and private decoration.

The Days of the Week.

On Saturday and Sunday the churches spoke the patriots praise. Sermons were on appropriate themes, and choirs sang patriotic anthems with thanks to God for the day. Special services of praise were held in some of the churches and the populace surged around the doorways unable to reach the densely packed areas within. Thus the week began with thanksgiving.

On Monday the incoming thousands from the country crowded the avenues of travel and the hotels were besieged for accommodations. Even the chairs in the waiting rooms were engaged and turned to temples of Somnus. In the early morning the throng tended upward, and took possession of the hillsides overlooking the scene of the

Bombardment

Which we illustrated last week. The hills were black with people, and when one considers the large stretch of surface which looks down upon this part of the bay, some little appreciation of the numbers can be formed. A little before noon the firing from the forts and ships began. The first shot was hailed with gladness by the throngs, and for three hours the crowd watched the puffs of smoke and the fall of the projectiles and heard the reverberation of the explosions. The firing of the guns contained many points of interest to the one unacquainted with such occurrences, but the general feeling was one of mild disappointment. The people expected and anticipated too much. Many expected, doubtless, to be well nigh prostrated by the thunder of the reports and to behold an exciting scene of circling vessels, belching broadsides, and a ship fired by the shots. The distance of the spectators from the guns made the reports but dull growling, the long minutes which intervened between the shots bore heavily, and the stationary frigates, which one expected would circle around their prey and seize it in exciting action, coldly and calmly fired for three hours and never once hit the mark which the throng was watching, and failed to fire the doomed craft until a small boat was sent out to apply a match. The absence of what anticipation pictured gave the bombardment a bad name in many a mouth, and yet if the beholder will recall the spirited scene upon the water, the fleet of small steamers flying hither and thither, decked with a multitude of people and clad in streaming flags, the three-mile flight of solid shot and shell and other interesting points which will recur to memory, the bombardment will seem a notable feature of the week's events.

The Sham Battle

Which occurred on Monday afternoon at the Presidio was more stirring and consequently more generally applauded. The evolutions of the infantry, the dash of the cavalry and the discharge of the field batteries won the full interest of the multitude and gave them a full taste of mimic war.

The Fourth.

The glorious day lost no luster from the stirring day of rejoicing which ushered it in. At an early hour the city was fully awake. The most intense excitement prevailed everywhere. The streets were soon overflowing with people, and numerous processions began to march in various directions, all clad in the gayest and and most gorgeous decorations, and forming to join in the procession of the day. By 10 A. M. the streets were literally lined with men, women and children thronging the sidewalks, sitting on the curbstones and stoops, and in every available position, while all the balconies and windows along the route of the procession were filled with fair faces and expectant eyes. Positions had been engaged weeks beforehand of the happy owners of a door or window along the line of the procession, and every room was filled by friends and acquaintances, who crowded in to witness the grand march. Multitudes had come in from the country, and the streets were literally blocked with a crowd which increased until room for more could not be had. The great procession which moved before the eyes of all was formed of at least 10,000 men. Civic, military, social and commercial organizations were represented. Trades were displayed by appropriate vehicles and decorations. Two hours were required to pass a given point, and the beholder turned away in a whirl of excitement over the changing scene.

The literary exercises which occurred in the Mechanics' pavilion after the grand parade were of a high and patriotic order. They consisted of an address by General Coey, prayer by Rev. W. H. Platt, oration by Rev. Dr. Stebbins, song by Mrs. Banta, and poem by Mr. J. F. Bowman. Afterwards a collation was served, at which addresses were made by Governor Irwin and others.

The remainder of the day was occupied with a carnival and with fireworks, torchlights and all the traditional glories of the old fashioned July Fourth.

The holidays were continued on Wednesday, the banks, insurance offices, wholesale houses, etc., remaining closed. The feature of the day was the regatta of the San Francisco yacht club, which was the most interesting ever witnessed on our bay. Some thirty yachts participated and they had all the wind they wanted. The largest of the schooner fleet, the *Cousins*, won the schooner prize; the old favorite, *Emerald*, won the prize for sloops; the *Lizzie* won the prize for second class sloops; and the *Annie* that for plungers. The race was well contested and excited great interest among the nautical portion of our population. Everybody has now settled down to work satisfied with the three days' holiday, and pleased to know that the celebration was so successful and that so few accidents of any kind occurred.

The Yellowstone Geysers.

There is probably no region in the world where there is such a variety of peculiar and wonderful scenery as in the Yellowstone country. It has as yet been visited by but few, and the only extended accounts of it which have been published are those furnished by the members of the U. S. geological survey, under Prof. F. V. Hayden. They have pretty thoroughly explored the region and given us many details concerning it. It may be taken as a very good indication of the wonders of this natural scenery that the scientific, matter-of-fact geologists and naturalists have described it at such length and praised it so highly. Fortunately for the people of the United States this extensive region has been set aside as a great National Park, where the land belongs to the people as a whole and no individual rights can interfere with the liberty of the tourist. Of course it will be some time before the railroad will render the Yellowstone country easily accessible, but we can rest with a consciousness that its wonders are not all perishable, and that at some day we will be able to visit and examine the most curious tract of country in the world.

The large engraving on our first page will give some idea of one of the special features of the Yellowstone, viz., the hot springs. The engravings were made for the *Christian Weekly* from photographs taken by Mr. Jackson, of the geological survey, and afterwards published in the report.

The entire Yellowstone basin is covered more or less with dead and dying springs, but there are centers or groups where the activity is greatest at the present time. On the south side of Mt. Washburn there is quite a remarkable group of active springs. The number of frying or simmering springs is great. Many of the dead springs are mere basins, with a thick deposit of iron on the sides, lining the channel of the water that flows from them. The steam vents are very numerous and the chimneys are lined with sulphur. Many of the springs seem to remain full to the rim of the crater, and are in a continual state of ebullition, and yet no water flows from them. Throughout this whole tract of country are hundreds and hundreds of geysers and hot springs of all characters and varieties. Some of them are in violent though intermittent action, while others are in a partially quiescent state. There are some that might be called spasmodic springs. The springs appear to operate perfectly independent of each other. Professor Hayden says he does not know that there is a connection between any of the springs in the whole basin.

The "Hot Spring Cone" shown in the engraving they called the "Fish Pot," from the fact that it extended out into the lake several feet, so that one could stand on the silicious mound and hook the trout from the cold waters of the lake, and without moving boil them in the steaming hot water of the spring. There seemed to be no connection between the orifice of the hot spring and the cold water around. In the upper right hand corner is the Castle Geyser and the most beautiful spring in the upper geyser basin of the Madison. The Grotto and Giant Geysers are first-class spouters, throwing a column of water up from 100 to 200 feet, and continuing the operation from one to two hours. The "Boiling Spring" at Sulphur mountain is in the valley of the Yellowstone, at the locality known as "Seven Hills." The open portion of this is about 15 feet in diameter. The ornamentation about it is beautiful in the extreme. At the lower right hand corner is a small sketch of the calcareous springs on Gardner's river, with the enormous terraces and bathing pools, which vary in temperature so the bather can find any degree he desires.

Mineral Fields of New South Wales.

The mineral fields of New South Wales are more extensive than most persons imagine. The proclaimed gold fields alone embrace an area of about 16,000 square miles, partly reserved from sale by the government for the purpose of public mining for gold. The total production of gold to the end of 1874 was £30,535,246, and the total value of gold coined at the Sydney mint to 1874 was £35 857,000. The approximate area of the coal fields is 24,840 square miles. The total quantity of coal raised up to 1874 was 12,387,279 tons, valued at £6,655.328. In 1874 they raised 1,304,567 tons. The approximate diamond mining area is 500 square miles, in which territory is included noble opals, ruby, sapphire, topaz, zircon, etc. The approximate area of lead and silver is 500 square miles. The approximate area of kerosene shale is 660 square miles. The total production of this substance in 1874 was valued at £261,414. The approximated area of the iron ore deposits is 1,400 square miles. The tin fields cover an area of 6,250 square miles. The total production of tin ore to the end of 1874 was £866,461, and the exports in that year were valued at £484,354. The approximate area of the copper mining region is 3,300 square miles. The total production of copper to the end of 1874 was £807,476, and the exports in that year were valued at £320,444.

Mineral lands in New South Wales may be leased from the government at the annual rental of five shillings per acre for a term of twenty years, renewable at the option of the lessee, or may be purchased at £2 per acre, on condition of spending a like amount within three years.

Placer County Mines.

[By our own Correspondent.—No. 1.]

Having made the rounds of El Dorado county, the American river was crossed on Lyon's new suspension bridge, three miles from Auburn. Two miles above the bridge, on the north side of the Middle fork, is situated the property of the Gold Bar mining company, on what is better known in this section as Mammoth bar, receiving its name, no doubt, from its unusual size. The claim is about three-quarters of a mile in length and from 100 to 300 yards in width, with a depth of gravel of somewhere from 30 to 60 feet.

There is every reason to believe that it will pay well if properly worked. Texas bar and many others above, and Murderer's bar not far below, are said to have filled the pockets of many an honest miner in days of yore. The amounts represented to have been taken out are almost too large to be realized, and are proceibly somewhat exaggerated. No one, however, questions their richness.

The bar, as far as prospected, if reports are true, cannot be far behind its neighbors. It is situated immediately below one of the richest gravel deposits in the State, and in the vicinity of some of our best seam claims and quartz ledges, where much gold has been found, set free from the decomposition of the quartz and sulphurets. The company has been incorporated with a capital of $10 000,000. There is ample fall in the river for power, and also for sluices. I understand that preparations are making to commence operations in earnest as soon as sufficient working capital stock can be disposed of for the necessary machinery.

From this point to Todd's valley and Yankee Jims, more or less mining is going on, both on the river and on the divide. There are one or two good quartz claims near Powell's ranch. The Sentinel shows a lode from 25 to 30 feet wide, and prospects well. Mr. Martin Martz was preparing to run a tunnel and put up machinery on the Spring Garden, a drift claim of the most promising character, having been already fully prospected. At Yankee Jims I met Mr. T. G. Durning, an old Placerville acquaintance, and the superintendent of the Union ditch, who gave me a full account of the mining operations in this vicinity for the past year, only a few details of which can be given. It seems that the mines had languished somewhat for the want of sufficient supply of water. After the Union ditch was finished, some two years ago, several new mines were opened, and new energy was infused into the community.

Although the new ditch has a capacity of 1,000 inches in addition to the former supply of water, still there is demand for much more, and there is evidently an opening here for the investment of a considerable amount of capital. At Mr. Lowell's, one and a half miles distant, a San Francisco company had just commenced operations on a fine gravel claim, from which you will probably soon hear favorable accounts. The claims of the Gilbert Brothers have paid good wages the past season, and some others have done well. The Georgia Hill claim, Nouges & Co., has a large bank of fine looking, lively blue gravel, that has paid remarkably well, $9,000 being cleared up in a 20-days' run, using a little over 1,000 inches of water at a pressure something upward of 300 feet. At Smith's point, almost within sight of the village, there are two or three very valuable gravel claims. Adams & Co. have a bank of 240 feet in hight that yields as much as $225 per day of 10 hours.

The claim of Cranage & Co. has a front of 1,000 feet; bank from 150 to 200 feet high. Pipe 11 and 15 inches, 700 inches of water, pressure 200 feet, and four men engaged and averaged last season from $150 to $200 per day of 10 hours' run. The yield this season will be considerably better. This company has a claim adjoining the Consolidated Washington not yet opened by hydraulic, from which it is said $500,000 have been taken out by drift.

Messrs. Pond & Constable, at Todd's valley, have been running five claims and doing a thriving business, employing usually about 30 men, using 2,000 inches of water per day, with a pressure of from 200 to 300 feet, and have a large supply of pipes of all sizes, and six little giants. Owing to the unusual supply of water the present season they expect to get a much larger return than last.

Within less than one mile east of this place Messrs. Wilson & Lawler have a good drift and hydraulic claim that pays so evenly that they can usually predict very closely the amount before cleaning up. Every run of six weeks yields almost invariably from $1,000 to $1,100. Seldom more than three men engaged. The claim is at present worked by drift, and there is a large bank to be hydraulicked which will last for 10 or 15 years.

The above would probably be classed among the Forest Hill claims, several of which are well spoken of, such as the Modoc, Big Spring, San Francisco, Hope and Baltimore; the two last named now at work, as also the Dardanelles and Oso. The Consolidation has a frontage of 2,200 feet, 1,600 feet opened and now being worked; bank from 130 to 150 feet high and extending one mile into the hill. This is one of the rich claims of this divide, having yielded up in the past at least a round million, according to the best information at hand, the books showing $150,000 in three years, and worked since 1853. It is at present and for the past four years has been averaging from $25,000 to $30,000 per season, according to supply of water, and is believed that this amount could be easily doubled with the use of larger and better machinery for working.

Two miles above Forest Hill there were originally perhaps upwards of 30 locations made of gravel mines at the bustling little village of Bath. They are now grouped together, and are held at this time principally by three companies.

Messrs. Clark & Co. have about 400 acres, prospected partially by two tunnels, which were too high. They are now driving another considerably lower, which will enable them to determine the true value of their ground. Owing to the hardness of the gravel and the difficulty of extracting the gold by means of sluicing and washing, little, comparatively, was taken out here in former years. Milling was next tried, which proved more successful, and now the hydraulic is resorted to almost entirely, a process of working far more remunerative than either of the other methods, as indicated by present results.

Roach & Co. have a front of 700 feet, bank 200 feet high and extending back about a mile; have taken out this season about $10,000. It is said here that $50,000 could have been turned out, but for a ditch that crosses the ground, which has temporarily stopped the work. Five hundred inches of water are used and from 10 to 15 men employed. Bedrock tunnel 500 feet and nine 30 inches, with a very fine outlet through a steep gulch. Iron riffles are exclusively used, instead of rocks or wooden blocks, as more dirt in this way can be run through, the flume easier drained up and more gold saved. The undercurrents are so complete and so well arranged for saving gold as to deserve more than a passing notice. There are four series of tables, iron riffled, with four different division or undercurrents in the upper table and two in other three. The last division in the upper table has clear water introduced to dilute the sediment and settle the fine gold. The pannings, black sand and sulphurets are passed through a simply constructed wooden concentrator—with an iron screen in bottom of box—and the riffles below filled with quicksilver.

The Paragon mining company, perhaps better known as the Bruce & Wheeler mine, lays claim to be the best gravel mine in the State. Front, 750 feet; rear, 1,900 feet; hight of bank, 300 feet; linear extent perhaps a mile; flume only two feet wide; 480 inches of water used; day shift, 10 hours; 20 men employed, and average yield per day $890. The last clean-up amounted to $30,000. The estimate for the season is in the neighborhood of $100,000. From a tunnel 1,600 feet long, $150,000 have been drifted out. The whole bank pays very evenly, averaging about 70 cents per cubic yard. A drift had been run along the upper lead 120 feet from bedrock to the distance of 4,000 feet, and the gravel when crushed paid very much the same throughout. A calculation based on these facts and present workings shows that the mine ought to yield $15,000,000.

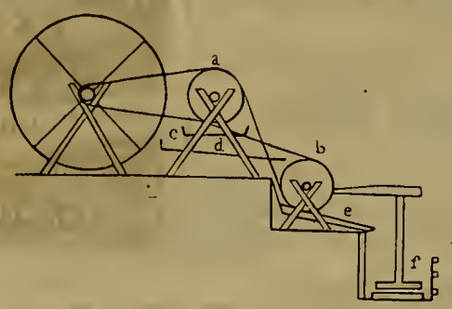
The information was received from the foreman and taken from the books, and believed to be fully reliable. No comment is necessary. The owners are practical miners and working men. There is no one so base as not to be pleased at a showing like this.

Both have also a quartz mine, and a good one: the Hancock & Watson, owned by Messrs. Dewey & Burt. The lode is from four to five feet in width. Thirty feet from surface it works about $7 per ton; at the 100 foot level about $13, showing that it grows in richness as depth is attained. They are stoping at present and have commenced to sink another 100 feet. The ore that has been crushed has paid very evenly, averaging $10 per ton. The whole cost of mining and milling has been about $5.50 per ton, showing a nice margin for profits. Five men drifting keep a 10 stamp mill running 10 hours per day. This is another of the paying mines of the county, and we are glad to be able to chronicle the fact.

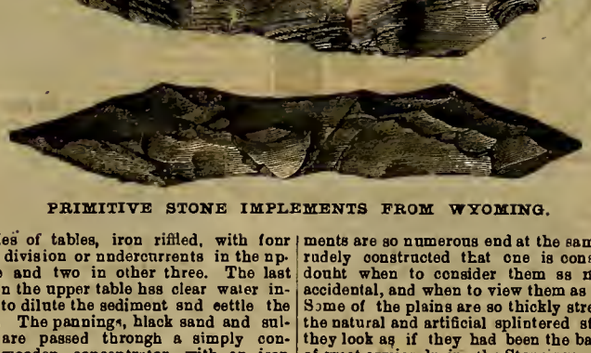
In one of the gulches, below two of the richest gravel claims described, there are several tailings claims, coming one after another, which are doing a good business. The Lehigh, at the upper part of the canon, the property of Hosmer & Co., saved one year 16 per cent. of what came from the claims above. This company expect to clean up this season about $10,000. They have three stringe of flumes, one of which is seven feet in width. So much for Bath. It will be difficult to find a mining town of the same size that is doing any better.

Remains of Primitive Art in Wyoming.

Professor Joseph Leidy, connected with the U. S. Geographical Survey, describes in one of the reports a number of specimens of the remains of primitive art in the Bridger basin of southern Wyoming. He says that in some localities the stones strewn over the lower buttes and plains are broken and flaked in such a manner as in many cases to assume the appearance of rude works of art. With these there are mingled implements of art of the rudest construction, together with a few of the finest finish. In some places the stone implements are so numerous and at the same time so rudely constructed that one is constantly in doubt when to consider them as natural or accidental, and when to view them as artificial. Some of the plains are so thickly strewn with the natural and artificial splintered stones that they look as if they had been the battle-fields of great armies during the Stone age.



A HOME-MADE QUARTZ MILL.



PRIMITIVE STONE IMPLEMENTS FROM WYOMING.

An engraving showing two views, one-half size, of one of these specimens of a prehistoric age, is given on this page. It is composed of gray and black striped jasper much weathered, and white and yellow on the surface. The question arises, who made the stone implements and when, and why should they occur in such great numbers in particular localities? The Indians know nothing of them and the Shoshones look upon them as the gift of God to their ancestors. They were, no doubt, made long ago, some probably at a comparatively late date, that is to say, just prior to communication of the Indians with whites, but others probably date centuries back. Their great number may, perhaps, be accounted for in particular localities from the circumstance that the neighboring buttes may have been especially the places suited for the materials of which the implements were made and the ruder ones cast aside. Stone arrow heads and numerous other implements have been found in the vicinity of Fort Bridger.

There is no prospect of passing this session the bill prepared by the California wine growers' association, introduced last December by Luttrell, for a reduction of the tax on native brandy and establishment of a bonded warehouse system for the benefit of fruit distillers.

A Small Quartz Mill.

From a "Practical Treatise on Testing and Working Ores," by Chas. H. Aaron," which is now in press and will be shortly issued, we take the following description of a small quartz mill for miners' use. The sketch represents a mill for working 200 or 300 pounds of rich ore per day. The large wheel may be a water wheel or treadmill. The pulverizing barrel, *a*, is a beer or wine cask, as is also the amalgamating barrel, *b*; the separator, *f*, is a large washtub. Beneath the pulverizing barrel is a sieve, *c*, to retain the balls or lumps of rock, the ore falling into the box, *d*. Under the amalgamating barrel, which is driven by a belt from *a*, is a trough, *e*, to carry the pulp to the separator, which is worked by a half twisted belt from a pulley on the shaft of *b*. The boiler for heating the barrel is not represented. In a larger affair the pulverizing barrel, *a*, may be replaced by a small arastra.

Perhaps the best way to utilize a very small power is to apply it all to one part of the process at one time. Thus, ore may be crushed for several days in succession, and then amalgamated in one day. In this way there are not so many things to attend to in one day, which is one of the difficulties of a small mill. Of course, however, the machinery to work a given quantity of ore per day must be larger than when it is all used at once. However, where only two or three tons of ore are worked per day, this plan must be adopted to some extent, in order to use a roasting cylinder to advantage. The power of two Chinamen or Indians, working turn about, will work 200 or 300 pounds of ore per day; that of two common horses, 400 to 500 pounds; and 60 miners' inches of water, or about 100 cubic feet per minute, on a 30-foot overshot wheel, with a mall battery or arastra, will work from two to three tons in 24 hours.

*——Published by Dewey & Co.; price, $2.

Book Notices.

Architectural Iron Work.—This work (for sale at Bancroft's) is a practical one for iron workers, architects and engineers, and all whose trade or business connects them with architectural iron work. It shows also the organization and mechanical and financial management of a foundry and shops for the manufacture of iron work for buildings, with specifications of iron work, useful tables and suggestions for the successful conduct of the business. The book is by William J. Fryer, Jr., and contains appropriate illustrations. The branch of iron manufacture treated of has increased largely within the past 15 years, and the probabilities are that the future will develop a still greater proportional growth. Good construction, economy of material and beauty of form in architectural iron work are important, and a knowledge of the subject requires diffusion. The author states that years of study, observation and hard practical work were the price of his thorough knowledge of this class of work; the aim in giving publicity to the knowledge thus acquired is largely for the enlightenment and advancement of workingmen. They need to have placed before them in plain and intelligible form an outline of how the works in which they daily toil are managed, and so to help educate up operative mechanics to become competent to command and control the coming great industrial workshops of the land. We should judge the work to be an excellent one for those in this line of business. The tables which the author gives in connection with his subject are valuable, and are conveniently arranged for reference. He seems to have gone thoroughly into the details of the business and has produced a work of great value to foundrymen.

California Notes.—This is the title of a little book by Charles B. Turrill of this city, and is, in a measure, a guide for tourists, although the author has compiled many facts of interest to the resident of the State. He treats of sections made familiar from personal observation, coupling with his notes of travel such information gleaned from standard sources as the size of the work would permit. This volume is the initial number of a series which Mr. Turrill proposes to issue on kindred topics. This one is especially devoted to the Mammoth Trees, Yosemite valley, the gold mines and San Francisco. The work was printed by Bosqui, and is, of course, neat in typographical appearance. The author has produced a readable little work, of convenient size for the pocket, and one which will be found of great interest to tourists.

High Masonry Dams.—This is the title of No. 22 of "Van Nostrand's Science Series." The subject is that of the profile of masonry dams of such hight, breadth and general dimensions as would be required for reservoir purposes, or for impounding the waters of rivers and large streams for mill or irrigation use. The author has avoided as far as possible all purely theoretical discussion, and has considered no forms of profiles that have not after repeated practical application demonstrated their excellence, even under the severest tests. The work is after the usual well known style of this excellent Science Series.

Telegraphic dispatches indicate that the Centennial Fourth was joyfully celebrated all over the Union.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly steemed and regarded by its readers; containing, as it oes, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot he found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO $5.

To Mining Companies.

A Mining and Civil Engineer of long experience, well acquainted with the superintendence of mines and mills, the projecting and construction of hydraulic works, machinery, etc., is open for re-engagement. Apply to Messrs. Dewey & Co., of the MINING & SCIENTIFIC PRESS, 224 Sansome street, San Francisco, for reference, or to J. ., Postoffice Box 633, Oakland, Cal

BOUND VOLUMES of the MINING AND SCIENTIFIC PRESS from Jan. 1st, 1864, are for sale at this office at $5 per volume, two volumes a year. Unbound at $3 per volume.

CHOICE VOLUMES.—We have a full new set of *Scribner's Monthly*—ten volumes—well bound, for sale at this office. Price, $2 per volume.

THE O'HARRA

CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
1500 lbs of salt at 1½c	22.50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

DEETKEN'S

ROASTING FURNACE,

For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 6 to 50 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adapted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING JUNE 27TH, 1876.

WATCH CASE SPRINGS.—Charles O. Fercoit, S. F.

FURNACES FOR STEAM BOILERS.—John L. Heald, Vallejo, Cal.

LUBRICATORS.—Nicholas Seibert, S. F.

AXLE SETS AND GAGES.—William C. Carlton, Boise City, Idaho.

PROPELLING CANAL BOATS.—Houston I. Chapman, Portland, Oregon.

BUCKET EARS.—Joseph F. Donkin, Grayson, Cal.

FRUIT DRIERS.—Hiland G. Hulburd, Placerville, Cal.

MARKING IMPLEMENTS.—Joseph Perkins, S. F.

BAG FASTENINGS.—Antone Rihn, Coulterville, Cal.

LINIMENTS FOR RHEUMATISM.—Clinton Skene and James Kearney, S. F.

ARTESIAN WELL BORER.—John A. Woodhouse, Anaheim, Cal.

DESIGNS.

PHOTOGRAPHIC MOUNT.—Isaish W. Taber and Thomas H. Boyd, S. F.

TRADE-MARKS.

FLOUR.—Savier & Co., Portland, Oregon.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency the following are worthy of mention:

FRUIT DRIER.—H. G. Hulburd, Placerville, El Dorado county. This invention is an improved machine for drying fruit, vegetables and other substances. It consists of an annular chamber which is arranged to rotate around a heating furnace and receive hot air from it. The hot air is received into the upper portion of the rotating chamber, and as it becomes charged with moisture from the substances being dried, it descends to the lower part of the chamber, and is discharged into the open air. The natural draft is used for drawing the heated air through the drying chambers, and the saturated air is renewed by its own gravity, so that there will be no forced currents to give uneven degrees of temperature in the chamber, and the fruit will be subjected to the gentle action of a uniform temperature. Where the fruit is subjected to an upward moving current of hot air, whether the fruit is carried towards or away from the greatest heat the air when it becomes saturated with moisture has a tendency to descend and will arrange itself in strata, according to its specific gravity or degree of saturation. The fruit is therefore compelled to pass from one degree of heat and moisture to another during its entire passage through the machine; whereas, many kinds of fruit, vegetables and other substances require a perfectly uniform dry atmosphere, and, the inventor thinks, should not be subjected to any great quantity of moisture during the drying process. This is illustrated, the inventor claims, by the power of this machine to produce perfect raisins from grapes, which it has accomplished in the most satisfactory manner. The fruit is subjected in this machine to a constant and uniform temperature of dry air, which is heated by radiation which will not eliminate the moisture too suddenly to overheat the fruit.

SHINGLE MACHINE.—Frank A. Huntington, S. F. In the first place Mr. Huntington has invented an improved arrangement for securing saw blades upon their arbors, which arrangement will be especially useful in a shingle machine, because it admits of carrying the bolt or block close up against the saw arbor and thus utilizing a greater portion of the blade, consequently rendering a saw of smaller diameter capable of doing the work of a saw of larger diameter when mounted in the ordinary way. He has also invented an improved arrangement for automatically operating the carriage which handles the bolt or block, and provided in connection therewith a novel feeding device and a stop for preventing the carriage from operating when the bolt or block has been sufficiently cut.

CONSTRUCTION OF WOODEN TANKS.—Edgar M. Morgan, S. F. Mr. Morgan's improvement in the construction of tanks consists in building up the sides of the tank of two or more thicknesses of overlapping boards, which are properly bent so as to be applied horizontally. It also consists in the application of an inside and outside brace at the base of the sides in the angles formed by the conjunction of the bottom and sides of the tank.

ARTESIAN WELL BORER.—John A. Woodhouse, Anaheim. Considerable difficulty has heretofore been experienced in boring wells for the reason that frequently at the depth of several hundred feet very hard rock is reached, in which the ordinary form of drill fails to cut a bore of sufficient size and regularity for the well pipe shoe to pass through. To obviate this and other defects, the inventor has constructed a drill which, by reason of an arrangement of automatically expanding or projecting side drills and chisels, and a main center drill below such arrangement of side drills, a bore of sufficient size and smoothness will be insured in every instance. When rock is reached which requires this construction of drill, it is coupled with the working shaft, inclosed within the shoe or lower cylindrical case of the well tube and sunk to the bottom of the well; after this the shoe is raised above the several series of side cutters and the operation of drilling commenced.

FIELD BOILER.—John A. Heald, Vallejo. This is an improvement in that class of boilers which are used for threshing engines and similar purposes. On the chimney of the boiler is placed a metal plate to deflect the wind in such a manner as to cause a good draft. Another improvement is in the construction of the door, which turns on horizontal hinges, and is made adjustable so that the opening can be made larger or smaller to accommodate any class of fuel—wood or straw as desired. There is also an arrangement of transverse tubes in the main flue which serves the purpose of diverting the heated air and prevents it striking the back plate, assisting it in returning through the smaller tubes to the chimney.

PARTITION BRICK.—Julee Borie, Oakland. This comprises certain improvements in hollow bricks by which they are rendered especially useful for constructing partition walls in buildings. Owing to their lightness, as compared with solid bricks, and to the fact that a circulation of air can be maintained through a wall composed of hollow brick, they are especially adapted for partition walls. The improvements consist first in such a formation of the ends of this class of bricks that the abutting ends of each two bricks in the wall will interlock with each other, and thus form a wall or partition in which all the bricks are bound together as a unit. Secondly, in providing in the sides of each brick perforations for holding the plastering of the wall and binding it firmly to the bricks.

BAG FASTENING.—Antone Rihn, Coulterville, Mariposa county, Cal. The improvement to which this patent refers can be adapted to bags and sacks of all kinds, but they are more especially adapted to grain bags. Metallic eyelets or rivets are used to fasten the corners of the sacks, and hooks made of best wire are used to fasten the mouth. The inventor claims to have provided a cheap and effective bag fastening, which can be readily manipulated and which will save much time in closing the mouth of the bag. We expect shortly to illustrate this invention.

MARKING IMPLEMENT.—Joseph Perkins, S. F. This invention relates to an improved implement or pen for marking heavy and light lines such as are usually formed with a broad marking pen or brush and colored liquid. The improved implement is especially adapted for writing or printing by hand directions upon packages and boxes, and for making figures, characters or sketches which are composed of alternate heavy, light and shaded lines.

MECHANICAL MOVEMENT.—Robert Swarbrick, Oakland. This invention relates to an improved mechanical device for converting a treadle or reciprocating motion into a continuous rotary motion. This mechanical movement is very cheap, and can be used in connection with a treadle instead of a crank for driving a sewing machine or such other machines as are usually driven by foot power.

MEDICAL COMPOUND.—Shane & Kearney, S. F. This discovery is an improved medical compound or liniment for the cure of rheumatism, gout and similar inflammatory diseases.

A LOCOMOTIVE SALUTE.—Among the specialities arranged for the Centennial celebration was one devised by Mr. Fellows, of the Central Pacific railroad, which was rather unique. On the morning of the Fourth, twenty or twenty-five locomotives were coupled together and backed up to Brooklyn on the overland track. Just at five o'clock they all commenced whistling in chorus and were run slowly down to the round-house, rousing nearly all the citizens of Oakland at that early hour to commence the celebration. The programme was kept quiet, and no one knew that anything of the kind was going to occur. The engines were decorated and presented a handsome sight.

VISITORS to San Francisco can spend a considerable time profitably any day in examining the wonderful and interesting things to be seen at Woodward's Gardens. The attractions there are constantly increasing.

IT is reported that an oil well was struck at San Francisquito, Santa Barbara county, June 23d, that flows 500 barrels a day.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANKS.]

F. Topaz.

This gem is generally found imbedded in primary rocks, commonly granite or gneiss with tourmaline, mica and beryl; but it is not unusual to find the crystals detached and free in streams with stream tin, as in Durango, Mexico, and at another locality 120 miles southwest of Salt Lake, Utah. A fine variety of smoky topaz comes to us from Arizona. The purest crystals are found in the Ural mountains, in Kamechatka, and in Brazil. There are several localities in the Eastern States but no fine specimens are found.

Different names are given to topaz of various colors, as follows: White with blush tinge, Siberian topaz; gold yellow, Brazilian topaz; wine yellow, Saxon topaz; saffron yellow, Indian topaz; rose red, Brazilian ruby; light blue, Brazilian sapphire; mountain green, aquamarine; greenish yellow, Brazilian chrysolite; limped or colorless, Nova Minas.

The Brazilian ruby is artificially colored by exposing a brown topaz to a dull red heat in a sand bath. The color is permanent.

The name topaz is thought to be derived from the island of Topazicon in the Red sea, where a yellow stone was found by the ancients. According to Dana this stone was not the true topaz, as it could be cut with a file. This gem was sometimes called "chysolithno" (golden stone) by the ancients.

The topaz occurs both crystallized and massive. Primary form of the crystals, right rhombic prism. Colors generally light; luster vitreous and splendent, transparent and translucent. Hardness, 8; specific gravity, 3.499, 3.641. B. B. infusible alone, with borax melts slowly to a transparent glass. Yellow topaz becomes rose red when gently heated. Dissolves slowly in bead of microcosmic salt, leaving the silica in a spongy state undissolved; dissolves in bead of soda and gives a blebby, semi-transparent slag, with more soda, swells and becomes infusible; when strongly heated, wet with solution of nitrate of cobalt, and again heated, it becomes blue, which is the reaction of alumina, streak uncolored. If the powdered mineral is mixed with strong sulphuric acid, placed in a clean glass tube and strongly heated, the glass will be attacked by the hydrofluoric acid set free. The best way to observe this reaction is to cut off the closed end of the tube, wash it out with water and dry with filtering paper.

The composition of topaz is as follows: Silica 22 3, alumina 54 3, silicon 6.5, fluorine 17.3,=100 4.

In making an analysis of topaz the silicon becomes oxidized to silica and gives an excess of weight, as will be seen by the following analysis of the yellow variety: Silica 34.01, alumina 58 38, fluorine 15.06,=107.45. There is also an error from a part of the fluorine being volatilized.

The topaz is pyro-electric; that is to say, it becomes electrical when heated. It may also be electrified by friction.

Although the topaz is really a beautiful stone yet it is held cheaply because it is not fashionable. A crystal the size of a bean is sold at the mines for $1 00, one pure white of one carat $8.00, a yellow one of the same size $3.00, a yellow burned one (Brazilian ruby) $5.00. In Brazil very fine stones sometimes sell for $30.

Aquamarine, chrysolite and quartz (false topaz) are sometimes sold for the topaz, but by studying the characterisiios of these different stones it may be with certainty distinguished from them.

The highest price on record ever paid for a topaz was $60,000. This stone belongs to the Great Mogul and weighs 157¾ carats.

G. Zircon, Hyacinth.

The zircon is a silicate of zirconia. Hardness, 7.5; specific gravity, 4 75; luster adamantine like the diamond; color, red, brown, yellow, gray, limpid, some times opaque, at others transparent; fracture conchoidal and brilliant. Composition when pure: Silica, 33.0; zirconia, 67.0,=100. System of crystallization tetragonal.

The zircon takes its name from jargon, a name by which it has long been known, and which signifies that although it much resembles the diamond it is comparatively worthless.

B. B. infusible. The colorless varieties are unaltered, the red becomes colorless, and the dark colored varieties change to white. Is decomposed if fused with alkaline carbonates or bisulphate of potash. If finely powdered and fused in a loop of platinum wire it becomes decomposed. If the bead is dissolved in dilute muriatic acid, the solution imparts a characteristic orange color to turmeric paper.

The zircon is found in crystalline rocks, as limestone, chloritic and other schists, gneiss, granite and sometimes in beds of iron ore. Found in alluvial sands in Ceylon, in the gold region of the Urals, in Transylvania, in Bohemia and numerous other European localities. It is not uncommon in the United States. In California it is reported in the auriferous gravel in the north fork of the American river.

The hyacinth is a zircon which is of a reddish orange color, having a shade of brown. The best hyacinths come from Ceylon. It is electric by friction. The colorless varieties are often sold for the diamond but it may be distinguished from its inferior hardness.

Zircon is sometimes calcined in a crucible with lime, when it loses its color and assumes the appearance of a pale straw colored diamond, for which it is sold.

The value of the zircon depends on purity of color, but it is not considered as a valuable gem. When the hyacinth is of a smoky white color it is called a jargon.

The zircon possesses the property of doubly refracting light to a high degree. It does not become electrical by heating.

The Tendency of Machine Manufactures.

Quite recently several able articles have appeared from the pens of mature thinkers, upon the social influences likely to be produced by the extended use of machinery. While we have felt a laudable pride in the triumphs of mechanical skill, yet many evils resulting therefrom are becoming alarmingly apparent. To such a degree has the facility for production been carried by the adaptations of labor saving inventions, as to almost sweep out of employment whole classes of heretofore useful citizens.

It seems to be a law of nature that men have a predilection or aptitude for different pursuits in life. One may be an admirable cabinet maker, while his twin brother delights in manipulating the iron upon his anvil. Another is happy in plying the shears and goose, and fitting the garment symmetrically to the forms of his customers. The devotees of St. Crispin have but little taste or adaptability to other pursuits, evinced frequently by some boy of the household who constitutes himself the custodian and healer of the foot dressings. The manufacturer of jewelry and the watchmaker must follow the proclivity that is a constituent part of their nature. And in the whole round of useful occupations we see displayed the beneficent scheme of the creator, that while these men are ministering to the necessities of others they are promoting their own happiness in such manner only as no other pursuits would obtain. As a rule, men must have employment in callings for which their temperaments, physical powers and innate tendencies have fitted them, or they will be a burden to themselves and to society. But a few years since, the fraternity of tailors constituted a very numerous class; now the iron nerves and sinews of the sewing machine has cast them ruthlessly aside. Not a tenth, no, not a twentieth of them all are to be found cheerily anipping the cloth or plying the needle. They are not only thrown out of their wonted and preferred employment, but they may well exclaim, with Othello, that their occupation is gone! Suppose they try to become carpenters; your machinery, planing machines, sash factories, door factories, blind factories and so on have played the deuce with them. All that is left over for that class of mechanics to do is to bring into place and adapt the various materials already prepared. Three or four will build a house as quickly now as twenty would have done but a score of years ago. Should our surplus carpenters turn their attention to shoemaking, there the sewing machine has again made a terrific onslaught, and together with other obnoxious inventions of the enemy has thrown four-fifths at least of their number out of their occupation, and they cannot adhere to their motto, "Let the shoemaker stick to the last."

The appliances of mechanism have invaded the precincts of manual labor in all directions alike. Even in agriculture, what with your gang plows, harvesters, threshing machines, mowing machines, etc., a large farmer will carry on operations successfully with a tithe of his former laborers. Aside from the great injustice done to these discarded men, what are they to do; whither are they to fly for support? From all quarters we hear the complaint that idle men are accumulating on society. This is no fault of the idle men; they simply have nothing to engage in for a livelihood. The men who mobbed and destroyed the first saw mills, and those who fought the first steam shovels, were only contending against a gigantic enemy who was endeavoring to oust them from their legitimate means of support, and they were correct in their philosophy.

Notwithstanding the difficulties involved in this question, political economists will have to grapple with it. In this connection, the oft repeated question, "What shall we do with our boys?" presents one of the most disagreeable phrases of the matter. All mechanical pursuits are practically shut off from them. All boys should learn a trade, it has been truly and wisely said. But the trades afford no field for an occupation, or only to but very few. What then? Agriculture? No. Farm products can only be proportionate to the home demand, as a general rule. Formerly such demand was caused by the necessity of all classes of mechanics at their own doors. The few comparatively who now engage in the other class of pursuits are congregated at manufacturing localities. It is evident that the unemployed, idle and vicious are fearfully increasing, and that to the foregoing causes are to be attributed this great evil. WILLIAM TEAL.

Bingham, Utah, June 22d, 1876.

SOME of those philanthropists who are devising plans for contributing to the comfort and improving the health of the poor, would find money expended in the purchase of GLENN'S SULPHUR SOAP serviceable in bettering the physical condition of the latter.

11th Industrial Exhibition,

Under the Auspices of the

MECHANICS' INSTITUTE.

The managers have the honor to announce that the forthcoming Exhibition will be opened to the public on

Tuesday, August 8th,

At 11 A. M., with the usual ceremonies. By the desire and co-operation of the leading citizens of San Francisco, the Exhibition will be held on a much grander scale than heretofore.

The Exhibition Building, Occupying an Area of over 214,000 Feet

Of floor room, will be completely filled with the varied products of the skill and industry of the people and of the soil. **Over 700,000 persons** were admitted during the last Fair. The managers intend to engage the services of the best instrumental talent of the country, so as to enable them to give unequaled

Musical Concerts Afternoon and Evening.

In every department applications for space for exceed expectations, and surpass those of former Fairs. Intending exhibitors must not delay filing their applications, otherwise they will be excluded.

The Exhibition will continue at least one month.

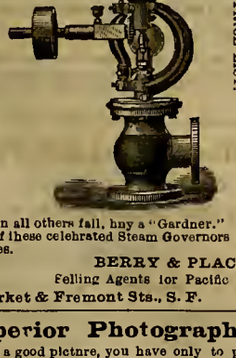
There will be no charge for exhibiting space.

Application for space or for information should be addressed to the Secretary of the Board of Managers, Eleventh Exhibition, 27 Post St., San Francisco, or to J. H. Gilmore, Supt., at same address.

A. S. HALLIDIE, Pres't.
J. H. COLVER, Sec'y.

The Gardner Automatic Safety-Stop Governor.

MORE THAN TEN THOUSAND NOW IN USE. EVERY ONE WARRANTED.



SEND FOR DESCRIPTIVE CIRCULAR AND PRICE LIST.

☞ When all others fail, buy a "Gardner." We have all sizes of these celebrated Steam Governors on hand at all times.

BERRY & PLACE,
Felling Agents for Pacific States,
Cor. Market & Fremont Sts., S. F.

Superior Photographs.—To be sure of a good picture, you have only to patronize G. D. Morse's Palace of Art, at No. 417 Montgomer street, S. F. The publishers of this journal have patronized Mr. Morse for many years, and do not hesitate to say that his pictures are not excelled by any we have seen produced in this or any other country. No one can ask for a better man to patronize than Mr. Morse. He is affable and respectful to all.

PACIFIC RURAL PRESS,

A first-class 16-page Agricultural Home Journal, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, $4 a year.

DEWEY & CO., Publishers.
No. 224 Sansome street, SAN FRANCISCO.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver. 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price $2.50 coin, or $3 currency, postage free. Published and sold at this office.

HENDY & COCHRANE'S ORE FEEDER

FOR QUARTZ MILLS,

AWARDED FIRST PREMIUM AT THE TENTH INDUSTRIAL FAIR OF THE MECHANICS' INSTITUTE.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the *carrier*, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane, or table, to the line of discharge, and there simply *dropped*. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says, of the Table Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."——A letter from Mr. O. C. Belding, of Amador County, speaks in the highest terms of them.——Two of the machines were shipped to the Bunker Hill Mill, Amador County. —— Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen.——Mr. Lachman, of the Soulsby Mill, Tuolumne County, says they work splendid; could not do better.——Two of the machines were shipped to the California Company, Nevada City. —— C. J. Garland, of Mosquito Gulch, Calaveras County, says: "I find them an excellent machine."——S. D. S. Stewart, Supt. Lincoln Gold Mining Company, says they are a perfect success.——O. C. Hewlit, Supt. Keystone Mining Company, says: "I can safely recommend them to all millmen."

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other machine of its class.

For Description, Send for Circular to

J. HENDY, Sole Manufacturer,

No. 32 Fremont St., - - - - San Francisco, Cal.,

WHERE IT CAN BE SEEN IN OPERATION.

HENDY'S IMPROVED AMALGAMATOR and CONCENTRATOR,

AND DEALER IN

QUARTZ MILL MACHINERY.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Amador Canal and Mining Company—

Location of works, Jackson, Amador county, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1), levied on the eighth (8th) day of May, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
T J Gallagher, Trustee	18	250	750 00
James Bolpb, Trustee	22	2500	7500 00

And in accordance with law, and an order of the Board of Directors, made on the eighth day of May, 1876, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of said company, on Wednesday, the fifth (5th) day of July, 1876, at the hour of two o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

J. W. CLARK, Secretary.

Office, Rooms Nos. 1 and 2, 418 California street, San Francisco, Cal.

POSTPONEMENT.—The above sale is postponed by order of the Board of Directors of the Amador Canal and Mining Company to the eleventh (11th) day of July, A.D., 1876, and will be held at the same hour and place.

J. W. CLARK, Secretary.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of June, 1876, an assessment, No. 36, of five cents per share, was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, Room 13, No. 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of July, 1875, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the 5th day of August, 1875, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

O. H. BOGART, Secretary.

Office, Room 13, No. 328 Montgomery street, Safe Deposit Building, San Francisco, California.

Hope Quicksilver Mining Company—Lo-

cation of principal place of business, city and county of San Francisco. Location of works, Cinnabar Mining District, Sonoma County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No 1), levied on the 12th day of May, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the 23d day of May, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at the office of the company, 13 and 15 Fremont street, San Francisco, on Monday, the 17th day of July, 1875, at 12 o'clock M., to pay the delinquent assessment thereon, together with the cost of advertising and expenses of sale.

L. L. ALEXANDER, Secretary.

Office, Nos. 13 and 15 Fremont St., San Francisco, Cal.

Mariposa Land and Mining Company

of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors held on the sixth day of July, 1876, an assessment (No. 6) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 8 Nassau street, New York.

Any stock upon which this assessment shall remain unpaid on the seventh day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the second day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEVANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Union Consolidated Silver Mining Co.,

San Francisco, June 15th, 1876.

The annual meeting of the stockholders of the Union Consolidated Silver Mining Company, for the election of trustees for the ensuing year, and for the transaction of such other business as may properly come before it, will be held at their office, 311 California street, rooms 3 and 4, second floor, over Ætna Insurance Office (entrance 309 California street), on Monday, July 17th, 1875, at 2 o'clock P. M. Transfer books will be closed July 12th, at 3 o'clock P. M.

J. M. BUFFINGTON, Sec'y.

Umpire Tunnel and Mining Company

Of Utah. Principal place of business, San Francisco, Cal. Location of works, Big Cottonwood District, Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 23d day of June, 1876, an assessment (No. 5) of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, 605 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 24th day of July, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 14th day of August, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

The ALLEN ENGINE GOVERNOR.

Uniform Speed in the Working of Steam Engines.

THE SIMPLEST AND MOST EFFICIENT GOVERNOR YET CONSTRUCTED.

ECONOMY and SAFETY.

Especially Valuable with Adjustable Cut-Offs. Capacity of Machinery Increased by Accurate Regulation of Speed.

Direct Saving of Fuel—Great Increase in Power of Engines.

Fig. 1. For Variable Cut-Off Engine.

The high rate of speed used acts advantageously in making the Allen Governor very sensitive; and all parts being lubricated, it works with the smallest amount of friction.

The speed of the Engine is maintained equally, without reference to the variations in amount of work being done.

The peculiar action of the Governor, which allows the use of a valve of large area, thereby admitting to the Engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced astonishing results by, being attached to old engines, greatly increasing their power or effecting a direct saving of fuel, and in hundreds of instances doing both. In running an engine with the Allen Governor with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Allen's Patent Governor Valve is constructed with a double disc in a tubular frame, and is perfectly balanced, there being no spindle as in the ordinary throttle valve to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, insuring the greatest possible durability.

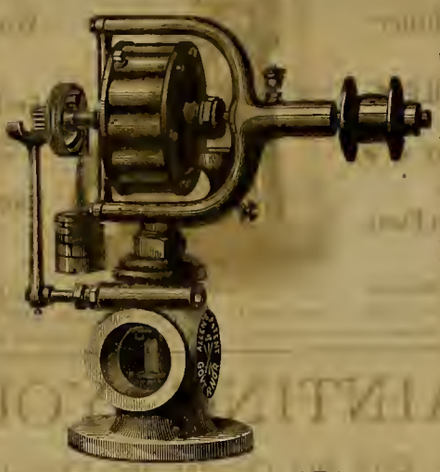

Fig. 2. Allen Governor and Valve.

We have Numerous testimonials from parties who have used this Governor, and watched its workings critically. In all cases the Governor has made the various engines to which it has been applied produce the most profitable results ever obtained.

Fig. 3. Section of Allen Governor.

PARTIES INTERESTED IN STEAM MACHINERY SHOULD EXAMINE THE ALLEN GOVERNOR, WHICH IS NOW INTRODUCED ON THIS COAST FOR THE FIRST TIME. FULL INFORMATION CONCERNING IT CAN BE OBTAINED FROM ILLUSTRATED DESCRIPTIVE CIRCULARS, WHICH WILL BE SENT ON APPLICATION. Address,

SODIUM AMALGAM.

I am prepared to furnish Sodium Amalgam for $1.50 per pound. Although the price is low, my reputation is a guarantee of its purity. Sodium being now much cheaper than formerly, the miner and millman should have the advantage of it. The temptation to adulterate the article being so great, consumers are advised to call for my manufacture when ordering from wholesale dealers, with an assurance on my part that the quality will be the best. Zinc is sometimes substituted for sodium, to the great disadvantage of the consumer. The following are the tests for pure Sodium Amalgam: Shaken up with water it must be wholly decomposed, the mercury remaining perfectly fluid and the water becoming strongly alkaline.

BEFORE PAINTING YOUR HOUSES

Send for Sample Card and Circular and Carefully Examine the

AVERILL CHEMICAL PAINT,

MIXED READY FOR USE.

This Paint is prepared in liquid form, READY FOR THE BRUSH. It requires no addition of oil or spirits. It is composed of the best materials known to the trade—Pure Linseed Oil, Strictly Pure White Lead, Pure Zinc, and the finest of coloring matter for tinting. It is the BEST, CHEAPEST, MOST DURABLE AND BEAUTIFUL PAINT IN THE WORLD. Is just what is wanted by every farmer, mechanic and everybody who has a house, fence, barn, or wagon to paint. Requires no skilled labor, as any one can apply it who can handle a brush. It is put up in cans of any required size, from a quart to five gallons, and is SOLD BY THE GALLON. It gives a firm, elastic and brilliant glossy finish, and will neither crack, peel or wash off, like most paint in common use, but is proof against reinstorms and all action of the elements. Buildings painted with this paint five years ago look fresh and like new to-day and will need no more paint for years. Of no other paint can this be said and proved.

The Averill Chemical Paint Company supply a long-felt want. They not only furnish a Paint more lasting, handsomer, and at the same time cheaper than the best of others, but it is in a liquid form—white and all the fashionable and most exquisite shades—ready for the brush. So that farmers, in fact everybody, can be their own painter if necessary. Indeed, all the buildings upon which the Averill Chemical Paint has been applied, are marvels of beauty.—*Christian Union.*

We know of no subject of such importance to householders as that of a good, handsome, durable paint for their dwellings. Within the past few years we have watched the progress of the Averill Chemical Paint and have had frequent opportunities to test it fully. We think it just the article to supply the need, and give it our hearty endorsement.—*N. Y. Independent.*

From the Thousands of Testimonials sent us, we select the following, which we present for your careful consideration:

A PAINT FOR FARMERS.—Prof. J. B. Turner, Jacksonville, Ill., is a man of great practical knowledge and experience; hence, we attach a great deal of value to the following, from his pen, which we find in the *Prairie Farmer:*

"Some two years ago I sent for and got from a barrel to a barrel and a half of Averill Chemical Paint, of light dun color, which I thought would suit me well enough for all work—houses, doors, blinds, fences, bee-hives, wagons, tools and all. I put two coats upon my residence here, and run over three or four of my smaller farm houses on my farms. With what was left I painted my bee-hives, wagons, wheelbarrows, rollers, harrows, fences, etc., etc. and on all these buildings, implements, tools, gates, etc., the paint is as hard and glossy to-day, so far as I can see, as it was a month after it was put on, and bids fair to hold its own at least for five years to come, (if not ten of them,) better than ordinary white lead and oil does for even two years.

"I have watched it now for about two years with interest and care, and have never found a single spot where it peeled, cracked, or chalked off, as our other paints do. Others who have used this paint like it equally as well. But the point is, I can take one and the same keg and brush, and go over all my buildings, wagons and tools, with no needless waste of paint, brushes or time. It is quite as good for inside finish, as it leaves a coat that shines and washes like glass."—*Moore's Rural New Yorker.*

THE AVERILL PAINTS.—In reply to some inquiries of our readers, we would state that we have given these paints, prepared by the Averill Chemical Paint Company, a full trial, and they appear to possess all that is claimed for them; spreading easily, adhering well, drying soon, and imparting handsome shades of color to the surface covered. Farmers and others who do their own painting, may avail themselves of the convenience of purchasing these paints, of any desired shade, already mixed for use, at a very reasonable price.—*Cultivator and Country Gentleman.*

PLACERVILLE, October 7, 1875.

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your letter I have to state that for more than six years I have dealt in and used your paint. I have during that time carefully observed its application and use, and from practical knowledge can certify to its unrivalled excellence. During my six years' acquaintance with it, there has not come to my knowledge a single instance of failure in any case where it has been used. All to whom I have supplied it unite in commending it for its superior claims over all other paints now in use. The Averill Paint externally used, or, in other words, exposed to the action of the weather, neither rubs off nor changes color, as do other paints, and will retain its freshness and adhesive property for years. Pure lead and oil will in a short time become dry, and are easily rubbed off; the loss of oil leaves the lead in a dry, oxidized state. As a matter of economy the claims of the Averill Chemical Paint to popular appreciation and general use are beyond question. A house properly painted with it once will be better preserved, and present a neater appearance at the expiration of seven years, than it would if twice coated with lead and oil paints now in use. There can be no question, then, that to use it is both labor-saving and economical. So well assured and convinced am I of its established right to this distinction over all kinds, that had I fifty houses of my own to be painted, the "Averill" alone should be my choice and used.

Yours, very truly, S. J. ALDEN, Druggist.

UNIVERSITY OF CALIFORNIA, BERKELEY, August 16, 1875.

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your note of the 13th inst., I willingly state that the work done by you in painting the exterior of the North Hall or College of Letters is in every way satisfactory, and the appearance of the building since it was painted excites the favorable comment of all who have seen it. As I have had occasion to use the Averill Paint before, my experience has been such that I prefer it to any and all others when properly applied. I am very truly yours, ROBT. E. C. STEARNE.

SAN FRANCISCO, SATURDAY, JULY 15, 1876.

VOLUME XXXIII Number 3.

Interest in California.

To the capitalist, the fact thet a high rate of interest rules in Californie, ie a enbject of congratulation, hut to the mase of the people it ie a great drawhack, as well as en impediment to the growth of the State. Capitalists do not care to nndertake the risks of hneiness so long as they can get a high rate of intereet on their money. Of couree no one can hlame them for this, hnt it is none the lese to he deplored. The maunfecturing intereete of the State of Californie have never heen npheld ae they ehould have heen for thie very reaeon. The mining and agriculturel interests have also felt the haneful effecte and there is eccrcely any hranch of hneiness which has not heen retarded.

Take it all in all the ruling rete of intereet in thie Stete may he coneidered as one per cent. per month, verying of course with the money market hut oftener going ahove than helow thet figure. The large horrower with *city* eecuritiee gets it cheaper eometimes, hnt the emall horrower with *country* eecurities never does. In fact it ie very difficult to get money at all from city capiteliste on property sitnated ontside of San Francisco. and when it ie procured it is at an edvanced rate.

The farmers here, as elsewhere, alwaye want money to pnrchnse sacks, implements, etc., end in this matter sre not always as independent ae the prevalent idea of their calling wonld imply. They are nearly always dependent for a temporary eupply of fnnds on the country storekeeper, for small local hanks are not as nnmerone as would he convenient, the hulk of money accumnlating in the city for reasons before stated. The storekeepere in the interior of thie State derive a large proportion of their income from thie ecurce, hut such high retes of interest are charged that it keepe the farmers poor to pay it. One and a helf and two per cent. per month are not hy any means nnusnal chargee, hnt money ie never procnred nuder these circumetances, for lees than one per cent.

The interest rate ie prohehly leee hnrdensome to the working miner than to the working farmer, for he takee out his money ae he goee along ae a general thing. But the mining intereets at large feel ite hurtfnl effects no less then the agricultural. There are hundrede of mines all over the country which could he worked to a profit could capital he provided to furnish machinery and properly develop them. But unless a perfectly enre five or eix per cent. per month profit is ehown to the capitaliste they wont tonch them. Ae to lending money on cleims, thet is out of the question, nnlese they are fully developed and have machinery and portahle property which will more than cover the loan, With inveetmente they muet have a controlling intereet or none at all.

This ieaside from stocks of conree and refers to legitimate mining enterprise alone. Ae to stocke of minee on the stock hoard, money can he procnred on them accordling to their standard and the etate of the market. But with what are called ontside stocks this is not alweye the case. It eeems somewhat etrange, hut is none the lese true, that money can he more easily procured on stocke that may he worth hundreda or nothing in a weeke time, than it can he on a farm with a permanent vaine.

More mannfactories are needed in this State to support a certain part of the popnlation, and to nitilize ite producte. Page upon page might he written to prove that millions are annually lost to us which might be saved, were different maufactories eetahlished. Every cargo or train of manufactnred articlee brought from other countriee help to keep idle our mechanics and decrease the wages of those who are already employed. We are importing every day manufactured articlee which conld he made at home, hetter and cheaper, and at the same time give employment to those who need it. As long, however, as the capitalist can eit at his desk and get one or one and a half per cent for his money, without riek or labor, he will not put it into any new mannfacturing industry. Arguments ahout huilding up the State or giving employment have no effect npon him, who cares nothing for either as long es he gets hie "cent per cent."

It is not, we contend, our increese of popnlation which caneee eo much idleneee and comparatively low wagee, hut the high rate of interest which prevails. California ought to support comfortahly five or ten timee as many inhehitante as are now within her horders. But hefore ehe can do it with credit, the rates of intereet must he lowered. Unlese this is done mennfactnring industry muet languieh, the mining interests will decline and the farmere keep poor. Capitaliets ehonld not make euch hroad distinctione hetween city and country property. They eeem unfortunately to he impressed with the idea thet nothing outside of San Francisco is worthy of finencial attention. If it were not for the interior of the State, San Francieco would amonnt to hut little, as ehe depends almoet entirely on the interior for her prosperity. With an inoreaee of proeperity in the interior comee a corresponding increese here, and onr capiteliete shonld rid themselves of any helief to the contrary.

The more mechanics, citizens, farmere or lehorere there are who come to reside with us the hetter it ie for the State, hut they mnst he found employment, which it ie the duty of the capitelist to provide. Leaving money at such rates that those desirons of estehliehing mannfacturing enterprises can get no profit, ie not fostering industry, as some persone seem to suppose, hut does more harm then good. When one faile nnder theee circumetances othere fear to make the attempt, and eo onr mannfactures are few to what they should he.

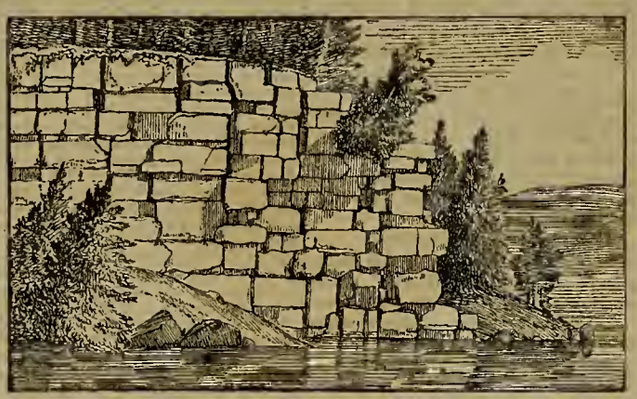
We mnst confe s, in conclusion, that we are in the same predicament as the horrowers, who eee no way out of it hut to accept the eituation, of which the capitalists have the hest. As long as they can get high rates of interest they will take them; and aa long as leuding money without risk pays better than inveeting it in husiuese enterprises, they will lend it. But the situation doee not impress one with any very exalted opinion of the California capitalist who may glory in the richness of the reeources of the State, hut does nothing whatever to assist in developing them. We shall continne thie euhject next week, and mention some of the reasons why capitaliete from ahroad ehonld he enconraged to extend their loans here, and how they can do it on a safe hasis.

THE Oakland harbor appropriation has been incressed from $75,000 to $95,000.

Avenues of Water for Hot Springs.

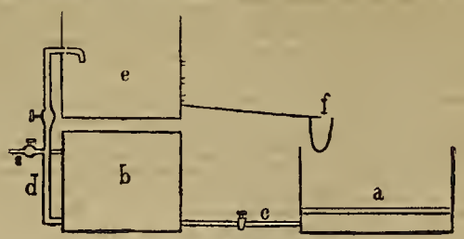
In epeaking of the origin of the remarkehle lake haein of the Yellowstone, in which the greatest part of the wondere is located, Prof. Hayden eeye it is moet intereeting in a geological poiut of view. He ie convinced it is not altogether one of eroeion hut in pert of elevation. It ie prohehle that the watere surrounded and perhepe covered the highest mountain peake. He concindes not only that the carving ont of the channel of the Grend canon was a very modern event, hut that the diepoeition of the entire meteriel which forme the canon is, in a geological eense, of quite a modern occurrence.

The drainage of the country commenced long before the excavetion of the present water



WALL OF BASALT, YELLOWSTONE RIVER.

conrses. Ae the watere slowly subsided, they were separated into lakee of greater or smaller size, and then came the excavation of the Grend canon, which elowly drained the great lake hasin above the falls. The hot springs, which are now elowly dying ont, are, of conree, the laet of thie eeriee of remarkahle physical eveute. The evidence eeema clear that all over the West during thie great period of volcanic activity the hot springs, and perhaps even geyeers, were very numerone. We everywhere find the remaine or deposite in all the States and Territories west of the Mieeiesippi, and now and then a warm or hot epring remaine to indicate the story of their former power.



AARON'S LEACHING APPARATUS.

An engraviug on this page is intended to illnstrate the prohahle avennes through which the meteoric waters pace down through the rocks to the heated portione. At Mud springs, about eix milee helow the Yellowstone lake, there is a vertical wall of hasalt about 50 feet high. Thie wall ie only a remnant of a vast mase which extended all along the river, hut which has now heen diesolved into clay of various colors hy the hot springs. The poiute are very regular.

THE white miuere on Jackass creek, Oregon, have commenced outraging the Chinese miuers on that stream hy hurning cahins and stoning them from, and taking poesession of their claims. A few daye ago a complaint was entered hy the Chinese that a man named John Miller, had shot a Chinaman and wonnded him in the hack, and a warrant for his arreet was placed in the hsnds of the eheriff for service.

Derricks for Hydraulic Mines.

At the gravel claim of Van Emen Brothere, Michigan Bluff, Placer county, they have four novel derricke in nee which they consider the best rigged end eesiest operated of eny in the State. A hrief deecription is eent to ne hy our correspondent in Placer county, which will he intereeting to eome of our readere, the mine iteelf heing deecribed in hie letter in enother colnmn:

One man eits at hie ease, attends the derrick alone, turns the water on and off, taking the dirt in and out and dumping the rocke without any aesistance, except from rope or pulley. It was wonderful. The improvement is the invention of Mr. D. L. Gorman of this plece. It ie specially neeful where there ie a head of water ae in hydraulic digginge; for the conetruction and attachment are euch that the force of the water is employed to raise the weighte.

The derrick ie monnted on a globe, out of which projects a pipe which furnishee the motive power, and by thns mounting it the whole machine can be turned in any direction without deranging the driving power. The pipe carrying the water ie diecharged into the lower part of the globe, which ie etationary. The npper half of the globe ia made with a flange, eo fitted ae to prevent the eecape of water. The two hemiepheree have an npright poet which ie festened at the hottom and extends through the top of the npper eection where there is a nut to hold the parte together, and yet allowe the npper hemisphere to turn independenttly of the lower. The mast and the friction wheel here ettached are supported upon the globe in euch manner ae to revolve with it.

Improved Leaching Apparatus.

From "A practicel Treetiee on Teeting end Working Oree" hy Charles H. Aaron, now in prese and ehortly to he issued from thie office, we take the following deecriptione of an improved leaching apparatus, invented by Mr. Aeron. In the engraviug, *a* is an ordinery leaching vat; *b* ie a wooden vacuum chamher; *c* and *d* are pipee, either of wood or rnhher, furnished with etop-cocks; *e* is a precipitating vat; *f* a flannel hag; and *g* a eteam pipe connecting with e hoiler. The ore heing placed in *a*, and saturated with the leeching finid, (the cock in c heing cloeed) the chemher *b* is filled with eteam, the air being expelled through *d* which ie open; *d* is then closed, and eteam shut off, when *c* heing opened, a vacnum is formed in *b* hy condeneetion of the eteam with which it ie filled. The preesnre of the atmosphere on the eurfece of the finid in *a*, forcee it repidly through the hed of ore into *b*; the cock c is closed, that in *d* opened, and eteam again admitted into *b*, and hy ite pressure forcee the eolntion through *d*, into *c*, where it ie treated with the precipitating agent, and when clear, ie drawn off end passed again to *a*, through the flannel bag *f*, hy which any floating particlee of precipitate ara retained. The hnlk of precipitate remaining in c, is then removed.

THE INDIAN WAR.—There ie very little news from the seat of the Indien war since that which hronght tidinge of the disaeter which reanlted in the death of the gallant Custer and his troops. It is evident, however, that the Goverument has a had Indian war to carry out. No volnnteere have been accepted, General Sheridan thinking that the regular troops are sufficient to quell the outhreak. Meantime every one ie anxione to hear of General Crook and his command.

THE Carhon silver mine, helonging to the mining company Nederland, of the Hagne, hae been attached for debt. It ie in Colorado, and was bought hy the Dntch company in 1870 for three millions of dollars. It has produced ahont $3,000,000 per annnm ever since, and ie considered ene of the most productive minea of Colorado. The mine is still enpposed to he rich, hut extravagant management has hronght it into difficulty. It has been managed entirely hy foreign mining engineere.

CORRESPONDENCE.

Placer County Mines.

[By our own Correspondent.—No. 2.]

From Forest Hill, by way of Bath, Michigan Bluff and Damascus to this point, (Iowa Hill) there is an immense gravel deposit, and some good gold-bearing quartz. Millions are looked up here awaiting the key of capital. Generally these mines are remunerative. Occasionally mistakes are made; some cases of mismanagement are heard of, and rarely some down-right swindling. It would be well for strangers to remember the old law maxim, "*Caveat emptor*," and take sufficient time for proper advice and

Examination Before Purchasing.

Many things are to be taken into consideration, such as water supply, out-let, and the channel on which the claim is located. Some of these are higher than others; have a richer and different deposit of gravel, varying in many respects, and of course requiring distinct methods of working. In view of all this, it is not much wonder that failures sometimes occur.

With the ordinary prudence and caution brought to bear in other kinds of business, there is a wide opening in this section for the profitable investment of capital. So much by way of introduction

After leaving Bath, where fewer idle men are found than in any other place of the same population in the mountains,

Michigan Bluff

Was next reached. The most productive claim at present worked is that of the Van Eman brothers, covering an area of about 120 acres.

The water season having just closed, it required no very keen sense of perception to see that they were by no means displeased with the result. This claim has been worked by hydraulic for 17 years, averaging from $25,000 to $30,000 per season. Although it has been giving out its gold for nearly 25 years, and is said to have yielded a million and considerably more, but a comparatively small portion has been worked out.

The gravel is mostly quartz, running from the finest through the cobble stone to the largest boulders. I send you with this a description of the novel derricks in use in this claim.

The Muir placer mining claim, as far as I could learn, lies east of the celebrated Bruce and Wheeler ground, and immediately west of the Weske claim, next in order to be described, and is thought to cover the same rich deposit. It has a slope down 105 feet, and from accurate survey has eight feet more to sink to reach the same level.

The Weske Gravel Mine,

Two and a half miles north of Michigan Bluff, comprises about 350 acres. A tunnel has been run in about 4,000 feet, at which point machinery amply sufficient for the work required has been put up for hoisting and pumping.

It has hitherto paid handsomely, sometimes as much as $30,000 being drifted out per month, requiring the employment of 15 to 20 men. It is looked upon as one of the best claims at present worked. Mr. Muir, who erected the machinery, and an experienced miner on this divide, says that they are now in or near the main channel, have eight feet of very fine looking gravel, and that by following the channel, taken in connection with the new and increased facilities for working, much larger returns may be expected within a few days.

The Red Hill hydraulic claim in El Dorado canon, coming next in order, has a bank of dirt and gravel 100 feet high, also, 50 feet of good drifting ground that pays from $6 to $8 to the man. A ditch has recently been brought in with a capacity of 400 inches of water, and a large reservoir to furnish the supply the year round.

One of the late and most promising discoveries is the Hidden Treasure consolidated, midway from Michigan Bluff to Damascus. From all accounts there was a nice little

Piece of Engineering

Connected with its opening. Mr. Cameron and others of the company, believing that the channel they were in search of was at the Mountain Gate at Damascus, (of which more hereafter), made a calculation by taking the level of bedrock in the tunnel of the last named at 75 feet fall to the mile, and from other observations in the immediate locality of their own mine, thereby enabling them to reach the desired point beneath the channel for drainage and working. An upraise of 30 feet at the end of this 500 foot tunnel brought them into a rich deposit of quartz gravel, that pays $9 to the man for ordinary working hours, which is looked upon by miners as a very fine prospect. It is a drift claim of 280 acres.

At Damascus, five miles north, is the

Mountain Gate,

With a width of 3,000 feet and a length of 10,000 feet—opened by a tunnel 5,800 feet, probably the longest in the State. This is in some respects

A Remarkable Claim,

Yet not so widely known as others of less merit. The object has not been speculation: The owners are working men. It has paid from the start. No assessment has been levied. Having been continuously worked since 1854, it has paid its regular monthly dividends. It has paid as high as $14 per day to the shareholder. The last year's payment was at the rate of $8.40 per share for each day, company time 280 days. The gross amount taken out last year was $65,000. The past month it yielded 400 ounces and the six months from January to July 2,100 ounces. Two hundred feet width of channel pays well for working, 40 or 50 feet of which would pay at least an ounce a day to the man.

An underground ride of upwards of a mile in hand cars, brought me into as fine a body of washed quartz gravel, to be found within the range of many a mile. In a portion of the works a channel of hard cement was pointed out, which was said to be at least 70 feet below the company's ground and something entirely distinct. It would make this article too long to describe all the curiosities to be seen here, but this much may be said, that a visit to the present workings some 700 or 800 feet from the surface will be amply rewarded for the slight attending inconvenience.

The Damascus Mill Company

Are at work on a parallel channel, composed of cemented gravel, about 70 feet lower at the mouth of the tunnel than that of the Mountain Gate. The company has a ten-stamp mill for crushing the cement, although not at present running. The dirt is now drifted out, and run about a mile through sluices and tail races passing on its way over three perpendicular falls from 30 to 50 feet in hight, which greatly aids in pulverizing the cement and setting free the gold. It is a claim that pays well. K.

[Editorial Correspondence.]

The Centennial at Philadelphia.—No. 9.

After spending some five or six weeks in close attendance upon the Centennial, your correspondent has left his post for a while, to attend to another duty equally imperative—that of visiting the "old folks at home" and spending a few days amid the pleasant retreats of his early years in eastern Massachusetts. What he has seen and learned there; the changes, progress, etc., of a quarter of a century or more, may form the subject of some future letter. From this distance he is of course unable to give in detail the progress or condition of things in Philadelphia, and instead thereof will endeavor to place upon paper some facts in regard to

The Peculiarities of the Centennial.

One of the chief peculiarities of this American exposition consists in the fact that, unlike the expositions of the old world, which have been expected to show merely the developments and progress which may have been made between one exposition and the next preceding, ours is called a "Centennial," and we are expected to show a century's progress, an effort which carries us back to the very infancy of modern mechanical appliances—to a point of time anterior to the faintest conception of many of the achievements in science and art which during the century have stamped themselves deep into the very existence of the present age. By the act of congress that has called into existence the commission which has inaugurated this exhibition, the American people were invited to show their progress during the century in the 'arts which benefit mankind, in comparison with those of other nations." This invitation gives us something of an advantage in point of historic interest over other nations, who have come hither as they have heretofore gone to London, to Paris and to Vienna, with those appliances only which tell of to-day—which show forth their perfected manhood, leaving *us* alone to contrast the great achievements of the present time with the germs from which they started "one hundred years ago." In this first Centennial period of our existence as a nation, it is natural to think of the past and strive to form some approximate idea of the real life and surroundings of those who participated in our struggles for national existence, and the early steps which were taken in the great march of material progress which has led to the triumphant results which we see before us in this great exhibition. The home life of our forefathers and the condition of the industrial arts one hundred years ago, are of much interest for our present consideration, made all the more so from the wonderful changes which have taken place during the past century—changes which during that time have wrought a complete revolution in almost everything which relates to domestic affairs and to the industrial interests of the world. History offers no other such marvellous spectacle, no other such example of the might, grandeur and progress of a nation. Therefore most fitting is it that on this anniversary we invite the nations of the earth to witness the triumph of art and industry, in the advancement of which our own people have performed so large a part. Although those who have had this great charge in hand have given us no cause to apologize for the general character of the entertainment to which we have invited the nations, it would seem to have been more in keeping with the call and the occasion had the exhibitors been instructed or encouraged to have more largely mingled the past with the present.

It is true they have done much in this direction, but with a little forethought much more might have been done to add to the interest and instructive character of the occasion. The progress of the spinning machine, from the primitive domestic wheel, might have been most profitably shown through all its principal gradations up to the present most approved machine. One of the rough and clumsy handlooms upon which many of our fathers wove the cloth they wore upon their backs, might have been most instructively placed in comparison with the light and elegant "jacquard" loom, which is to-day weaving, in machinery hall, elegant Centennial mottoes, with most perfect portraits of Washington, Victoria and other distinguished personages. So of the lathe and all the various machines for working in wood and iron. It would be interesting to look upon the clumsy contrivances originally used for hulling and ginning cotton, and be able to compare them upon the spot with the perfected machines now in use and on exhibition. The old lesthern fire-buckets, to use which at a fire we old men, when boys, had to "form a line," and the antiquated hand engine of the same period should have been shown in contrast with the brightly burnished steam fire-engine of the present day. We would like also to compare the bright steel blades of the Ames' shovel, as shown to-day, with one of the old tools which, 40 years ago, the writer was accustomed to see the present millionaire turning out with his own hands—his father working in the shop by his side.

One hundred years ago there were but two steam engines in the United States—one of which was running a small pump in a brewery in Philadelphia and the other pumping water from a shallow copper mine, just across the river, in New Jersey. What more interesting sight could have been shown than the intermediate steps by which these primitive machines have been gradually developed into the magnificent Corliss engine, which now stands out so prominently in machinery hall as one of the mechanical marvels of the day.

The First Locomotives in America.

The few pieces of antiquated machinery which are shown at the Centennial are just sufficient to create a desire for a more general exhibition of that character. Near the English exhibit, in machinery hall, there are several pieces of old iron, which the ordinary visitor would suppose were thrown aside for transportation to the junk shop, but which the more careful observer learns, from the label attached, are sacred relics, and all that remains of the first locomotive ever placed upon a railroad in America, called the *Stourbridge Lion*, built in England and placed upon the Delaware and Hudson railroad on the 8th of August, 1829, at Honesdale, Pa. What remains of this interesting relic are four tires and two hollow iron beams, the use of which latter, about a locomotive, would be difficult for any modern engineer to divine. In the engineering department, in the front gallery of the main building, is also shown the original drawing of the first American built locomotive ever put together, and which was first run on the Charleston and Augusta road, in South Carolina, on the 25th day of December, 1830. It was called the *Best Friend of Charleston*. The second built American locomotive, the *West Point*, was placed upon the same road on the 5th of March, 1831, less than three months later, at which time and place the writer of this letter was present. The wonderful progress that has been made in perfecting the locomotive and in advancing transportation facilities during the 45 years that have intervened since the dates above given, are among the marvels of the age.

Relics of Early Steamboat Experiments.

Near by the drawing above alluded to, in the gallery of the main building, may be seen the original boiler and twin screws built and operated by Stevens; also a second pair of screws, subsequently experimented with on a somewhat larger scale. They were mere models in size, designed for propelling nothing larger than an ordinary sized sailboat. There is also shown, in immediate connection, the remains of what we believe was one of Fulton's small boilers, used in his early experiments. These relics possess an interest of no ordinary magnitude to the engineer and student, and we think they will be preserved to grace the next Centennial, when, perhaps, even steam itself will have been superseded by some more potent or convenient motor.

Other Relics.

The first steam fire engine ever constructed is shown in the main building. Franklin's printing press—the one on which he is said to have worked in London—is also shown in the same building, and in the department devoted to the exhibition of printing presses and material. This department comprises one of the most interesting and instructive exhibitions shown, from the fact that by it the visitors may trace all the steps of progress from the old "Ramage" through all the various kinds of hand and power presses up to those marvels of perfection, the American Bullock and the English Walter press.

In the agricultural building we have also a few relics illustrative of the progress which has been made in the construction of agricultural implements. We have an old plow from Killingworth, Conn., said to be 120 years old, at least. The handles are made of roots formed by nature in the proper shape for such purpose. The mold board is of wood with an iron point. This plow was once used to turn up the virgin soil of old Connecticut; but is now preserved with the greatest care as a remarkable relic of the past. Another plow with a peculiarly elongated wooden mold board is shown bearing the date of 1776; and still another very ancient one from Ohio. These ancient relics of the olden time present a marked and interesting contrast with the polished steel blades and elegant woodwork of the modern instruments which are shown by their side. A similar exhibition in connection with other agricultural implements would have formed a most interesting and instructive study.

Among the relics of more modern days is a plow said to have been made on Daniel Webster's old farm at Franklin, N. H., and under the personal supervision of the great Granger-statesman himself.

Remington exhibits, in connection with his show of fire arms, the first breech-loading rifle ever made in the United States. It was made at Harper's Ferry in 1826. It is a "flint lock;" the chamber being raised by a spring, and hinged at the hind end. The cap is raised from the pan and the piece primed in the old way. This weapon is exhibited as the intermediate step in the manufacture of fire arms between the old flint lock musket and the modern breech-loaders and revolvers.

The Centennial System of Awards.

Another peculiarity in which the American Centennial differs from all previous international exhibitions is in the system of awards which has been adopted. It has been urged, heretofore, that the prizes and awards were too cheap; that the wish to be popular and not give offence has prompted the managers to bestow many medals that were not deserved, and which were conferred in classes whose preeminence had been taken on merit, but were considered vitiated by the repetition and multiplication of honors bestowed where there was no display to deserve them. At the Centennial there are to be no medals awarded. The substitute therefor and the general plan of awards is given in a report of the Executive Committee as follows:

"Awards have generally been made by an international jury of 600 members. The apportionment of jurors to countries was tried on various bases, but was usually made on the basis of relative space occupied by products of each country respectively in the exhibition. The great jury was divided into numerous small juries, who examined the products and prepared lists of names of persons whom they proposed for awards, and the proposals thus made were confirmed or rejected by higher juries. This system brought together, unavoidably, many individuals unqualified for the work. The basis of representation was apparently fair, but its results were delusive. The countries nearest the exhibition occupied the largest space. Numerous remote countries filled smaller spaces. The number of jurors allotted to the latter body left them in many instances without jurors on many classes, and thus in voting on awards they had no voice, and the awards were in effect decreed by the few contiguous countries. Written reports were not usually made by juries, and if made, were not printed, consequently no person outside the jury knew on what grounds awards were made. Medals, when distributed, were silent verdicts, and awards thus made conveyed little useful information. Awards were based upon anonymous reports or reports not published, and final decisions were recorded in vague and mystic language not satisfactory to producers or the public.

"The method of awards adopted by the Centennial commission differs from this system. It dispenses with the international jury, and substitutes a body of 200 judges, one-half foreign, chosen individually for high qualifications. It dispenses also with the system of awards by graduated medals, and requires of the judges written reports on the inherent and comparative merits of each product thought worthy of award, setting forth its properties and qualities and presenting the considerations forming the ground of the award. Each report must have the signature of its author. The professional judgment and moral responsibility of the judges being thus involved, the integrity of the reports is assured. The success of this method absolutely depends upon the judicious selection of judges." W. B. E.

SOUTHERN UTAH.—A correspondent of the Salt Lake *Tribune* says: Star, San Francisco and Bradshaw districts are now making every effort and will, no doubt, shortly command the attention of the great mining companies of the world. The steady increase of bullion of a high grade, which is now being shipped from the Shumar smelter, is a sure criterion to go by. Since last winter, regardless of bad roads, the want of coal and other materials to run, this smelter has turned out nearly 2,000 tons of bullion, which will assay from 170 to 200 ounces silver per ton. Refractory ores have been worked successfully under the skillful management of Mr. Harting, and he has truly made a great success in this district.

CALIFORNIA GRAPES AT THE CENTENNIAL.—From October 10th to 14th is the period especially designated by the Commission for the display of grapes at the Centennial; and as California can easily excel every other locality in the Union, if not in the world, with this particular fruit, her large grape growers should make their calculations in good time so as to make a large and expressive exhibit of this luxury for which their vineyards are so celebrated. The Golden State has not, thus far, particularly distinguished herself at Philadelphia, even in her specialty of precious metals; but she will have an opportunity to redeem her character during the grape display, a month before the Centennial closes.

MECHANICAL PROGRESS.

Fac-Simile Telegraphy.

The one thing wanted in telegraphy by which a meseage may be practically transmitted over a wire and appear at the distant terminus in the *exact handwriting of the sender*, has at last been accomplished by an American electrician, Mr. W. E. Sawyer. The field opened to the telegraphic world by this invention is almost without limit. The instruments are wonderfully simple in construction and easily comprehended. The system is capable of transmitting over a single wire from 50 to 150 words per minute, against a possible 30 or 40 by the Morse system, which is that now in common use. But by this system a person's own handwriting is transmitted by telegraph the same as though sent by mail, and, in brief, simply accomplishes letter writing by telegraph. In order to render its operation fully understood it may be described as follows:

First, the sender of the message writes it upon ordinary white paper; the written message is then laid upon a metallic plate and passed between two rollers, with the effect of transferring the copy to the plate, which may be done any time within ten hours after writing. Then the plate containing the copy is placed upon a semi-cylindrical holder which traverses the little track, and the instrument is set in motion, the whole operation up to this point having been accomplished in less time than it takes to write it; whereas, by the Morse system, quite a number of minutes elapse before the message reaches the operator. The metallic plate is a conductor of electricity, while the lines of writing are non-conductors. Over the cylindrical plate are carried metallic points upon revolving arms; whenever the point is upon the metallic surface, the electric current passes through to the wire; the instant the point touches a line of writing, the connection is broken and a dot is made upon chemically prepared paper, placed upon a similar instrument at the receiving point. The two instruments operate synchronously—i.e., the moment a point is passing over the surface of one instrument, it is followed exactly by the point on the other instrument. An ingenious mechanical arrangement perfects the transmitting powers and prevents the possibility of one instrument gaining over the other. At the same time the points are moving over its surface, the plate is moved slowly horizontally, so that the entire surface is traversed. The transferred message is, of course, in reverse, but is brought straight by running the receiving instrument in an opposite direction. Each instrument is fitted to either receive or transmit, at pleasure. The rate of speed varies according to the closeness of the writing; the pointe traversing the entire surface of the copy, it is immaterial as to the number of words, only the space they occupy requiring a given time to be gone over. Ordinary writing will be transmitted at the rate of from 50 to 100 words per minute.

The message, as received, is ready at once for delivery, and appears in close, dark blue dotted lines, on white paper. There is no loss of time in counting the words at the sending station, as is now the case, nor delay in getting to the hand of the operator; but, in a quarter of a minute's time from its being received, it is silently speeding its way to its destination, and automatically preparing itself for delivery. The wonderful facilities of the system render it peculiarly adapted to a large and hurried business. It is the fruit of many years' close application, hence the perfection with which it makes its appearance.

The writer of a message is, of course, as usual, supplied with blanks. In the system proposed—and which is now being perfected by the company already formed to utilize this great invention—for whatever may be written upon the blank he will pay an invariable sum of money, if under 250 miles; if over, double that amount in stamps, to be furnished by the company, and used the same as postage stamps. Whatever is written upon the blank, whether five words or 50, will be sent for the same amount. It is so much blank passing through the instruments, and no cognizance is taken of its contents.

A company called "The United States Postal Telegraph company" has been incorporated under the laws of the State of New York for the purpose of constructing lines and operating under the letters-patent granted to Mr. Sawyer. —*Boston Journal of Commerce.*

JUMPING THE TRACK.—To prevent the accidents to which railroad trains are liable from one car jumping the track, the plan has been devised of applying to cars a kind of shoe, consisting of a clamp-like arrangement which is affixed between the wheels of each truck. This runs about two inches from the rail, and if any thing happens tending to throw the wheels from the track, the clamp at once grasps the rails, holds the car on the track, and brings the train to a speedy halt. Such a shoe will, it is claimed, prove a great saving of railroad rolling stock, and add greatly to the strength of the truck, it being constructed of iron, and weighing some 500 pounds. Experiments made with cars provided with this device, show that the arrangement accomplishes very effectively the object in view, and it is estimated that on account of the additional strength thus imparted to the car, it must last much longer.

Dullness in English Ship-Building.

The London *Iron* notes much depression in the great ship-building port of Great Britain. It says: As the months roll onward, the amount of work in the ship-building yards and marine engineering establishments of the Clyde becomes rapidly diminished, and there is no saying when there will be any improvement to record. Compared with the condition of the two staple trades of the Clyde three or four years ago, or even more recently, that into which they have now passed is one that is exciting a very great amount of anxiety and even despondency in the minds of those most interested. To the outside world, however, the fact of the very dull state of the ship-building industry does not seem of itself to be at all abnormal, inasmuch as almost all other leading branches of industry are in a similarly depressed state.

Somewhere about 30 vessels of various sizes and kinds were launched last month, but exceedingly few orders were booked to build new vessels on the stocks thus left vacant; indeed, the past month has been one of the least fertile on record in bringing out new contracts, and those that have been booked are of comparatively little importance. In ordinary times there was rarely ever a storm at sea but what was shortly afterwards followed by a number of orders for new vessels to replace those lost in the storm, but now there is a totally different condition of things. During the month of March there were 115 sailing vessels lost, of which nearly 50 were owned in the United Kingdom, and 15 steamers, of which more than one-half were British; but the rule now with regard to the replacement of such vessels is to purchase others that have already seen service, but for which remunerative freights cannot possibly be obtained, or such as have been built on speculation and are lying idle in the hands of the builders. There are still a few yards that are tolerably well occupied with vessels in progress, but in other instances, unless fresh orders come to hand in the interim, the month of September will bring about a complete clearance. Certainly there does not seem any prospect of orders coming to hand, as the ocean-carrying trade is at an exceedingly low ebb.

DECISION ON A MECHANICS' LIEN.—A decision rendered by the United States circuit court at Davenport, Iowa, a few days since, in the case of the Delaware Railroad Construction company vs. the Davenport and St. Paul railroad, and involving some $300,000, possesses much interest. It appears to settle, so far as that particular court is concerned, one feature, at least, of the vexed question of mechanics' liens, and in favor of bondholders as against parties constructing a road. In the case mentioned, the construction company claimed a mechanics' lien on 25 miles of road, for work performed, and judgment had been rendered in their favor by the court below, and the road had been sold to satisfy the judgment. The United States circuit court, to which the case was appealed, decides that a mortgage to secure the payment of bonds takes priority of all mechanics' liens, and, as we are informed, in this case, also, holds that the construction company having accepted securities in the shape of town subscriptions along the line of the road, is by that act also shut out from all right to a mechanics' lien. The case will be taken up to the supreme court of the United States.—*Railway Age.*

SPANISH SWORDS.—During the visit of the Prince of Wales to Madrid he was shown the Fabrica de Armas, where are manufactured the far-famed Toledan blades, which are as celebrated as those of Damascus. This manufactory is on the banks of the Tagus, and was built and fitted up with forges in 1788 to 1798. Here all the bayonets and swords for the Spanish army are made of steel so finely tempered that the sword can be bent almost into a curve without snapping. The Prince of Wales seemed especially pleased with this *fabrica*, where His Royal Highness proved some of the blades and warmly praised their workmanship. The Prince took away a sabre and some other specimens, and one piece of steel, to show its metal, was absolutely bent into the form of an 8. The sword, or rather rapier, now being made at Toledo for General Stanchez Bregna, as a present from the citizens of Madrid, was then shown to the Prince. It is a most elaborate work of art, perfect in finish and metal, and was greatly admired.

NOVEL SKATING RINK.—A skating rink of highly polished white marble, and 18,000 square feet in extent is being laid down in the suggestive vicinity of the Orphanage, Clapham road. A fall upon asphalte is bad enough, but nothing to the cropper which an awkward or unlucky tinker would catch upon a marble slab. It is announced that the usual refreshment rooms will be provided; the addition of a well-furnished surgery would be a no less suitable provision.—*Iron.*

ETCHING ON METAL.—The *Metallarbeiter* recommends etching with a preparation of 250 grammes of perchloride of iron, which is allowed to slowly decompose in half a litre of water. The advantage of this preparation is that it has an effect on metals of all sorts without giving off noxious vapors. The object will need constant cleaning with a brush. The solution is rectified with oxide of iron when choked with metal, the etched ground is cleaned with turpentine.

SCIENTIFIC PROGRESS.

Insects and Plants.

In the Philadelphia papers we note full reports of a recent discussion before the Academy of Natural Sciences on the question of cross-fertilization by insect agency, between Mr. Thomas Meehan and Professor Asa Gray. Mr. Meehan remarked that there was no doubt that some plants have flowers which, so far as we at present know, are incapable of self-fertilization and are fertilized only by the agency of insects; but he differed from his friend as to the extent to which these facts prevail and in the interpretation of the facts. A large number of flowers are fertilized by their own pollen that are claimed as illustrations of the other view, and he did not know how far these errors had prevailed; and then he thought that the fact was patent that self-fertilizers had maintained their hold and fought their way through the world and through the ages as well as or better than those which exhibit what is claimed as a "horror of close breeding." Scrophularia had been so claimed; but *S. canina* was a fertilizer. The anthers were folded back in the corolla and one by one straightened out, carrying the anther to the apex of the pistil, where the pollen was ejected. The pollen was of a beautiful orange color, and it could be seen by the naked eye alone that none of the stigmas had pollen till they received it each from its own flower. Referring to the dandelion, he said the pistil grew through the mass of pollen, carrying a quantity with it. Reaching its maximum growth, the pistil curved, making a "pot-hook," then cleaving at the apex first on the upper side, spread its lobes out in finally opposite curved arms, its own pollen falling in at this first cleaving of the apex. Ox-eye daisy is a similar but still more easy way, self-fertilized. Independent of this, he urged that in many localities where sweet flowers were abundant winged insects did not visit these two flowers to any extent. In his vicinity, for instance, he had never seen any on these two species. He made the point that, even though one composite flower was fertilized by another in the same head, he thought that physiologically flowers side by side in a composite head were as much brother and sister as anything that could be brought up from higher life. The physiological value of such cross-fertilization, he thought, must be drawn to a very fine point. As regards the red clover, which is said to have such nice arrangements for cross-fertilization, even to the exclusion of the honey-bee and for the exclusive use of the humble bee. Mr. Meehan said the humble-bee did not enter the mouth at all, but collected the honey by slitting the tube from the outside. Professor Gray replied to Mr. Meehan that when he spoke of Scrophularia, in "How Plants Behave," he had reference to *S. nodosa;* and he described how he understood that species to act when in flower, and was sure, from that behavior, that that species could not fertilize itself. The facts pointed out by Mr. M in *S. canina* were in some respects new to him; but he felt sure that a careful examination would show his friend to be wrong, and that it did not fertilize itself. In regard to dandelion, numerous insects visited it, near him; and, though he would not say it might not occasionally fertilize itself, he was sure it had to be in most cases fertilized from other flowers in order to seed. And he had no doubt that was true of ox-eye daisy also. Clover he said he had never examined critically himself, with a view to its bearing on these questions; but he would do so the coming summer.

New Rays of Calcium.

Mr. Lockyer, in a letter to M. Domas, says: I have recently carried out a series of experiments upon calcium, employing at first a small battery and a small coil, and afterwards a large battery and a larger coil, and to avoid all doubts I photographed the results. I found that with the small coil I was able to obtain a photograph which only contained the ray in the blue, without any trace of the ray in the violet; and with the largest battery and the largest coil I obtained a photograph containing the rays of the violet without any trace of the ray in the blue, and that by varying the surface of the battery I was able to get a spectrum resembling the absorption-spectrum of calcium in the sun.

These results agree so completely with those of the dissociation of a salt of calcium that I have asked myself the question if we have not here before us a dissociation of the calcium itself. Naturally we are unable to determine, for the present, whether we have a lower molecular group of calcium, or whether the calcium itself is a compound of two distinct subelements, if the expression may be used. It seems that we can only undertake to solve this question by photographing the rays of the calcium (H_1 H_2) in different stars. If we find that they present always the same relative breadth and intensity there will be a strong presumption that we have met with a decomposition of calcium, or, in other terms, we shall have shown that a spectrum of rays is a spectrum due to different orders of molecular groping. If, on the other hand, we find that these lines vary in breadth and in intensity, it will be difficult to explain this phenomenon except we admit that calcium, instead of being an element, is really composed of two substances.—*Comptes Rendus.*

Science in Schools.

A few weeks ago Professor Huxley delivered a lecture on the method of teaching science in schools to the Edinburgh local branch of the Educational Institute of Scotland, in the Watt Institution, Chambers street, Edinburgh. Mr. Manrice Patterson presided, and there was a large audience. Professor Huxley commenced by showing how teaching of science was carried out when the object of the teacher was simply to teach science, and when he was embarrassed by no other consideration. The system of teaching science, like all wholesome things, had grown out of practical necessities. In almost all cases science was an outcome of all art. People had begun to feel the necessity of systematizing the rules of the art, and for developing them to their farthest extent, and those rules had become what we now termed science. This was eminently the case with the science the teaching of which first became properly organized—the science of anatomy. They must not trust to the teaching merely, and to the advantage gained from its being supplemented by books or aided by diagrams. In order to have the kind of knowledge which was real, and could he depended upon, it must be acquired by the person taught going over the matter which he had to know for himself, and learning it at first hand. To this end were dissecting-rooms established, where the student himself verified what he had been told. Scientific teaching was in a great measure the acquainting the man with the laws which govern the phenomena of nature; but, in addition to this, there was about it the value of educational discipline. The first importance of its value in this sense was the fact that it cultivated the faculty of observation. He knew of no pursuit which was so competent to conduce to culture as science. The tide in favor of the introduction of science into schools was flowing as fast as it could, and if those who opposed themselves to it did not get out of the way they would be swept away. The extent to which they might carry this teaching of science would, of course, depend entirely upon the time allowed. He would be quite content with an hour. In conclusion, he observed it was most necessary that the person who teaches should know what he was teaching.

A New Tanning Process.

A joint stock company was formed in Detroit in March last, with a capital of $100,000, for the purpose of manufacturing leather by a new process invented by a tanner named Richter, and already about 3,000 hides have been turned out. The leather is represented to be soft and flexible, and when manufactured into shoes one upper wears out two or three soles. The process does in two to six weeks what the old process requires six months to one year to accomplish. Under the old process the hide lies in the vat with the bark for many months, the longer the better, gaining firmness and strength with the lapse of time. By this process the tanning is done in an hour, and all the time spent is that required for carrying and dressing. The process is a chemical one, performed by the action of certain inexpressive chemical materials, the composing of which in the right proportions is a secret. Hides, tanned with the hair on, are soft as the finest wool; hides of the deer, horse, dog, etc., are smooth and soft, while calf and kip show the texture and grain which good shoemakers most admire. Another great advantage is the economy of the process, no bark being required, except a little to give the proper color to the leather. Bark is worth eight to nine dollars a cord, and about 200 cords are required to tan 1,000 hides by the common method. Two cords would be sufficient to give the proper color to the same number of hides, and the saving in this item will be enormous. The Detroit works, with a force of 15 men are turning out from two to three thousand hides per month.—*American Manufacturer.*

PHOTOGRAPHIC MAPS.—At a meeting of the Edinburgh Photographic Society, Mr R. H. Bow read a paper on "Small-scale Maps for Tourists." The reader remarked that the tourist whom he had in view was one who judiciously combined pedestrianism with the use of the abundant means of rapid conveyance from one district to another. To such a one, well informed of what he should see, and when and where to look for it, a good map was indispensable. His difficulties and discomforts in using a folding map were often so many that rather than open it he would allow himself to pass unheeded places of interest along his route. This could be changed, as by means of photography all that a map contained could be put into the compass of one or two pages of a guide book. It did not appear to him unreasonable to expect that the ordnance survey maps might be reduced to a scale of four or five inches to the mile, so as to comprise in one page of portable size the sheet measuring in its original form 24 by 18 inches for the real map work. Mr. Bow mentioned that the Typographic Etching company had been endeavoring to carry out his notions in this respect. He showed specimens of the work done for him by that company, and also a copy of No. 25 of the ordnance survey maps, in which the scale was reduced to nine and one-half miles to the inch. In this latter the word "station," near Melrose, was only one-fortieth of an inch, and the hight of the letters one three hundred and fiftieth of an inch or less, and judging from the distinctness it was evident that lettering one five hundredth of an inch in high could be legible under a cheap lens.

Gold, Legal Tenders, Exchange, Etc.

[Corrected Weekly by SUTRO & CO.]

SAN FRANCISCO, July 12, 3 P. M.

LEGAL TENDERS in S

The Mining Share Market.

The downward movement in stocks has continued with little variation, and nearly everything is lower than it was a week since. A great many persons who are supposed to be heavy operators have been compelled to sell out in order to save themselves, and, of course, small dealers have suffered as well. As is always the case when there is such a sharp decline, rumors of the failure of several merchants and capitalists are circulated, but as yet they lack confirmation. The action of the market too plainly indicates that there is a great struggle going on for the supremacy, and in the fight many a supposed strong one will go under before the contest is decided. The great points of attack are Consolidated Virginia and California—the bonanza group—and every device is resorted to by the "bears" to weaken the confidence of the public in them. How and when this contest is to end is at present impossible to tell, but it is hardly probable that others than the bonanza group will be much affected, even if the market should not take a change. Large sales of Consolidated Virginia and California have been made, and it is naturally thought that some of the large operators have been forced to sell.

The Comstock mines are all looking and yielding about as usual. From the bonanza mines there were shipped on the 6th, 136 bars of bullion, weighing seven tons and 1,810 pounds, and worth $522,655.75. This is the largest single shipment ever made from the Comstock. The mines were all shut down on the Fourth, except the pumps, in order to allow the men to celebrate the Centennial Fourth. The majority of the mills also shut down. Only enough men remained at the mines and mills to guard them. Much new machinery will go into operation next month, more than in any one month in the history of the Comstock, and all will be of the finest and most powerful description.

The Mining Law Amendment.

The following is the full text of the amendment to section 2324, of the United States revised statutes, passed by the House, and to which we made reference last week:

The miners of each mining district may make regulations not in conflict with the laws of the United States or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked upon the ground so that its boundaries can be readily traced; all records of mining claims hereafter made shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims located by reference to some natural object or permanent monument as will identify the claim. On each claim located after the 10th day of May, 1872, and until an application for a patent therefor and final proofs and payment for the claim have been made, as required by the terms of this chapter, not less than $100 worth of labor shall be performed or improvements made during each year. On all claims located prior to the 10th of May, 1872, $10 worth of labor shall be performed or improvements made by the 10th day of June, 1874, and each year thereafter for each 100 feet in length along the vein, until an application for a patent therefor and final proofs and payment for the claim have been made, as required by the terms of this chapter: Provided, That where an application for a patent has been filed in the manner prescribed by this chapter, and an adverse claim asserted against the same, and suit commenced thereon, the annual expenditure for labor or improvements herein before prescribed shall not be required until the right and title to such claim shall have been finally determined by a court of competent jurisdiction; but where such claims are held in common such expenditure may be made upon any one claim; and upon a failure to comply with these conditions the claim or mine upon which such failure occurred shall be opened to relocation in the same manner as if no location of the same had ever been made: Provided, That the original locators, their heirs, assigns or legal representatives have not resumed work upon the claim after failure and before such location. Upon the failure of any one of several co-owners to contribute his proportion of the expenditures required hereby, the co-owners who have performed the labor or made the improvements, in writing, or notice by publication in the newspaper published nearest the claim, for at least once a week for 90 days, and if, at the expiration of 90 days after such notice in writing or by publication, such delinquent should fail or refuse to contribute his proportion of the expenditure required by this section, his interest in the claim shall become the property of his co-owners who have made the required expenditures.

It should be stated that this bill has not yet reached the Senate, as far as we know, and may not even be considered by that body this session. In the House, Mr. Page opposed the bill on the grounds that the present mining law was substantially correct; that under this new bill the law could be evaded by inducing others to file counter claims; that different methods might be adopted to avoid labor and expense, awaiting the development of other adjacent mines, and in the meantime the general development of the country would be retarded. Mr. Maginnis, of Montana, agreed substantially with Mr. Page, but argued that this bill in no way interfered with local mining laws. That it was simply a proposition to amend section 2324 so as to clear up and make explicit some of its provisions. That the object of the bill was to give equal protection to the miner who has fairly represented his ground, paid his thousand dollars and made his final proof and payment at the local land office; that the certificate he then receives shall be as good to him as to the farmer who makes entry of agricultural land, and shall not be compelled to further work his ground on account of the delays in the land office over his patent. In other words, it relieves the applicant of the yearly payment of $100 after he has proved up and paid for his mine, and during litigation, until he knows whether it is his claim or not. There is considerable difference of opinion among miners as to the merits of the bill, and we would be glad to see it discussed by different parties. Our columns are open to those who desire to express their sentiments on the subject.

Mining Accidents.

Four mining accidents have come to our notice the past week, by which as many men lost their lives. The first one was at the Rock Island mine on the Comstock.

John H. Parkinson, chief engineer, accompanied by a miner named John Prout, started to come up on the north tank, Prout standing on the west side of the tank and Parkinson on the east side. Three bells were sounded, so that the engineer knew that there were men aboard. Just before the cage reached the head of the shaft the engineer shut off his steam and attempted to put on the brake, and all at once discovered that the brake-bar had been thrown out of its guides by the under-bar which comes up to set the brake. He stooped down to fix it, and at that moment the cage with the two men appeared above the top of the shaft. Parkinson saw that something was the matter and called out to Henry H. Clarke, the engineer, to reverse the engine. This excited Clarke to such a degree that he was unable to do anything at all, so the cage, with the tank and the two men, passed on up out of the guides, and Prout's head was crushed between the cable and the pulley-wheel on which it works, more commonly known among miners as the "sheave." Parkinson's arm was around the cable and was caught between Prout's head and the pulley-wheel, where it was held for more than half an hour. Prout was instantly killed. Parkinson's arm was terribly bruised and mashed, but no bones were broken. The reason the cage continued to ascend after steam had been shut off was that the north and south cages were connected, and that the weight of the descending cages forced the one carrying the men up, beyond its proper place.

On the 2d inst. a miner, named Elisha Cocking, met his death in the Savage mine. He was working in the pump shaft on a platform, and gave the signal to hoist, when he had attached the steel rope to a heavy iron pump rod. The rope was new and caught, knocking the platform from beneath him and precipitating him down the shaft about 200 feet, killing him instantly.

Frederick Renz, a partner in the hydraulic claim of Clark & Co., Railroad flat, Calaveras county, was instantly killed by the bank falling on him.

John Le Blonde, a miner, working in the Imperial mine, on the Comstock, was killed on the 8th instant, by striking his head against the timbers while coming up on the giraffe.

WASHINGTON TERRITORY COAL FIELDS.—A line of the Northern Pacific railroad is contemplated from Tacoma, on Puget sound, up the Puyallup river a distance of 30 miles. General George Stark, General Manager of the North Pacific road, is now on his way to Tacoma to examine the route of the proposed road and report to the directors of the company. Should this road be built it will penetrate the coal fields owned by the company, and enable consumers on this coast to procure fuel at a great discount from the prices now charged. The company has sent experts, who are thoroughly conversant with all qualities and kinds of coal, into Washington Territory, to make a thorough examination of the deposits, and they report that the quality of the coal to be obtained from these fields is far superior to any now produced on this coast. To give an idea of the scarcity of good coal on the Pacific slope, it is only necessary to state that during the year 1875, as much as 140,000 tons were received in San Francisco from Australia alone. As the Pacific Mail steamship company's steamers penetrate Puget sound and touch at Tacoma, the facilities for transportation to this port will be excellent.

A CONTEMPORARY estimates that there is about $20,000,000 of gold coin in this State in circulation at the present time, and that there was only some $10,000,000 at the time of the bank panic, last August.

THERE are 2,005 children of school age in Virginia City. In Storey county there are 3,002 children. There are no deaf, dumb or blind children in the county.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

NEW ENGINE.—Alpine *Chronicle*, July 8: Manager Chalmers, of the Exchequer mine and mill, is preparing for a vigorous campaign in mining operations, now that the stability of the mine is assured. He has sent the 40-horse power engine that has been doing duty at the mill to the mine to take the place of the one now in use, which will be transferred to a new claim, upon which work will soon be started. The cylinder having been sent to San Francisco for repairs, several days will elapse before the new works will be in running order. With this engine the loaded cage can be raised from the 400-ft level in one minute. Mr. Chalmers has contracted with the Vulcan iron works, of San Francisco, for a new engine for the mill. It is intended to be about 120-horse power, with a cylinder 18x22 inches, and to be shipped in 30 days from signing of the contract. With the new engine additional stamps, soon to be put in, and the new O'Harra furnace, the Exchequer mill will be one of the best appointed reduction works of its size on the Pacific slope. The mill and furnace will be in successful operation by the 1st of September, and there will be no lack of ore to keep it running steadily.

THE ADVANCE.—This shaft is down 275 feet, and the seams are pitching east with the ledge. We visited the mine on Thursday and found men engaged in grading a site for an addition to the hoisting works, to accommodate the new machinery.

THE FURNACE.—Brick is being hauled to the site for the O'Harra furnace, to be erected at the Exchequer mill. It is expected that the furnace will be getting out bullion on or before the 1st of September. It is a consolation to know that this is not another Alpine experiment. The success of this style of furnace at Peavine has dispelled all doubts as to its ability to work our ores.

AMADOR.

POSEY HILL MINE.—Amador *Ledger*, July 8: This mine is located on Dry creek, in the northeastern part of the county, about ten miles from Volcano. It is owned by Mitchell & Campbell, and was discovered only a few months ago. A shaft has been run down to a depth of 95 feet, the ledge in the bottom showing two and a half feet in width. There is a small quartz mill close to the property, at which some of the rock has been crushed, yielding, we are told, over $20 per ton. They are now engaged in fixing up the mill to run by steam power. It is the opinion of experienced miners who have inspected the property, that the owners of the Posey Hill have alighted on a spot that will put them in circumstances of affluence in a short time. That these golden anticipations may be more than realized is our earnest wish, as both men deserve such a stroke of good fortune as much as any men in the county.

CALAVERAS.

GWIN MINE.—Calaveras *Chronicle*, July 8: The Gwin mine continues to produce largely. The last clean-up, after a few days' run, amounted to over $10,000. A hundred tons of rock are daily put under the stamps; all operations connected with the mine being prosecuted with ceaseless activity. The sinking for the 1200-ft level has reached a depth of 80 feet, and will be completed in about a month. The Gwin is now the best paying gold quartz mine on the coast, and its future prospects are as flattering as its present is propitious.

QUAKER CITY.—We are glad to be able to state that fair grade ore has been struck in the Quaker City quartz mine, located at the Junction. The 200-ft level has been run a little over 20 feet from the shaft, at which point good rock was struck. Work in the level has been delayed somewhat by foul air, but that difficulty is now obviated and labor is progressing actively. The mine is under the supervision of J. H. Reed, Esq., a thoroughly practical man, and we have an abiding faith in its future.

UPPER COUNTRY MINING JOTS.—At West Point times continue lively, mining operations being briskly pushed. Champion, sinking. The richest ore ever found in the mine is now being taken out, and the ledge is wider than at any point above. Sinking continues at the Josephine. We hear favorable reports regarding the quality of ore being extracted. A mill is being put on the mine, which it is expected to have in running order within two or three weeks. Fields & Co. are hauling rock to Carlton's mill. We learn that they have something like 50 tons of high grade ore.

GLENCOE DISTRICT.—Sinking is being vigorously pushed at the Hadlock mine. The shaft is down about 90 feet, the ledge showing three and a half feet wide. A lot of rock from Needhan & Co.'s mine, crushed in Garland's mill, paid upwards of $22 per ton. Hauling rock from the Herryhausen mine to Garland's mill either has been commenced or will be next Monday morning. The rock is good, and we expect to be able to chronicle a good clean-up as the result of its crushing.

INYO.

DEFIANCE MINE.—Coso *Mining News*, July 8: The most work is now being done on ledge No. 3. The north stope on the vein is improving every hour. The ore on the back vein is seven feet in width without a particle of waste and of the highest grade of carbonate, chloride and galena mixed. The south drift on this vein is also in splendid ore. This vein is a total terror, or, as an enthusiastic miner declared to us in confidence, "She's a hird entirely, partner." We are informed, just as we are going to press, that the ledge has been struck in the main incline, where the hoisting works are erected, and that the ore is a superior grade, resembling the ore in ledge No. 2. The strike was made yesterday morning. The assay value of ore in the main incline is $124 silver, and 60 per cent lead. That is the splendid body struck in the main tunnel, third ledge, assays in silver $205 and 75 per cent lead.

DEFIANCE FURNACES.—The furnaces have been running extremely well the past week, as the following figures will show: Shipped during the week ending last night, 687 large bars and 143 small bars—total, 730. Remaining on hand, 40 large and 229 small bars. The bullion is of high grade, and is likely to still increase in value as depth is reached in the mine, although the percentage of galena is quite sufficient for successful smelting.

LEE DISTRICT.—The news from this district is quite cheering. The developments on the Emigrant company's claims prove that the predictions we have made in former issues will be more than realized. The mill is running smoothly. The ore taken from the mines without assorting, pulps $150 per ton. No clean-up has yet been made, but from assays made from tailings they are working up to 80 per cent. of the pulp assay. Mr. I. M. Taylor informs us that they have recently secured a water right in some springs that are at such an elevation that a pressure of 400 to 600 feet can be obtained. It is his intention of laying pipes at once to bring this right to the mines, which will do away with the necessity at present existing of hauling water.

NEVADA.

MINING ITEMS.—Nevada *Transcript*, July 9: The Providence mine never looked better than it does to-day. The ledge is large and is filled with gold bearing sulphurets. There is an ore body opened up that will require years to work out. It is expected to have one of the Fryer processes put up on it as soon as the machinery can be completed. The old Soggs mine, which is on the north of the Providence, and a part of the same ledge, is looking first rate now. A rich pay chute was struck some time since and has no signs of giving out. The rock is taken out by contract, and the men have been making double wages for months. The California and Gold tunnel also have a large ledge, and rock that pays well. The two mines, which are owned by one company, have increased in value every day as they are further developed. The gravel mines hereabouts are all running with full heads of water, and we understand big clean-ups will be made at the end of the season in those that are not cleaned up monthly. Prospecting is going on in several places with good indications of opening up paying mines. Up in Washington township there are several splendid developments being made. The mine owned by the Coleman brothers and others, is thought by the best judges to be one of the best mines in the county. There is a good deal of prospecting going on up in that section since the new road affords opportunities to get into the district with teams. Those who have recently visited the place assure us that Washington township will soon rank as one of the best quartz mining districts in the county. The ledges are all very large and prospect well. In all parts of the county everything looks encouragingly, and bids fair to be one of the most prosperous seasons for years.

THE Yerba Buena mining company who own claims on the range above the Cold Spring ground, have commenced running an incline for the purpose of opening out the channel supposed to run through there, or, in fact known to do so. If some more of the companies that own on the line of the channel would commence work, it would not be long before times would be lively on the ridge.

NEW YORK HILL.—*Foothill Tidings*, July 8: The rich pay chute in this mine is said to be pitching towards the old works and it has been decided best to move the machinery to that point for future operations. The stoppage of work for this purpose throws over 100 men out of employment and is therefore to be deplored, but from all we can learn it is pre-eminently the best course to be pursued and will likely be the making of the mine.

SAN BERNARDINO.

BEAR VALLEY.—Cor. San Bernardino *Times*, July 2: The 40-stamp mill is running day and night, and crushing about 60 ton of rock every 24 hours. The present owners of the mill, Messrs. Holmes & Parson, seems to be well satisfied with the result of the two clean-ups, and if the next month's run should be as satisfactory as the past they intend to put up 20 more stamps. They have the timbers all ready and ten more stamps already on the ground. They expect to make a good profit on $8 rock, although they have not worked on any of so low a grade as yet. The water to supply the mill is brought about seven miles in a flume; and the ore is taken from the mine directly to the mill in tramway care. The town contains about 40 buildings—some very good and substantial.

SIERRA.

CLAIM ROBBED.—*Mountain Messenger*, July 8: We are sorry to learn that the mining claim of Jas Alexander, near Deadwood, was robbed a few days since of nearly all the gold washed out this season. He was washing through a ground sluice, and left it all right Saturday night, but when he returned on Monday morning he found that he was out and injured. The robbers had over 30 hours in which to do their work, and they improved their time. We do not know the extent of the loss, nor do we know whether the robbery was committed by white men or Chinamen, but it was probably by Celestials from Poker Flat, as there is a bad lot of heathen thereabouts.

TUOLUMNE.

BLACK HAWK.—Tuolumne *Independent*, July 8: George Morgan, of Columbia, the owner of this fine plumbago mine, after two years work, has finished the tunnel to the shaft, were it strikes the lead 50 feet from the surface. The tunnel and open cut is 700 feet in length. The lode at this point is over 200 feet wide; and increases in value as depth is attained. About 300 feet further, the tunnel will strike a point on the vein from 700 to 1,000 feet from the surface. There are thousands of tons in sight, and Mr. M. is making shipments all the time at good prices, there being a good demand for it. Several parties have been trying to purchase the mine for the past two years, but as yet they have not agreed to reach the price fixed for a sale of the property.

THE Soulsby mine yielded for the month of June, $23,000.

Nevada.

ELY DISTRICT.

LOCAL MATTERS.—Pioche *Record*, July 2: During the past week there was shipped by Wells, Fargo & Co., $7,510 in bullion, it being about the amount shipped during the previous week. Nothing has been stirring in mining circles with the exception of the starting of subscriptions for a smelting furnace, and the proposed building of another furnace by Mr. Smith, of Shaunticleer. This will have a tendency to induce miners to prospect considerable, besides giving employment to a large number of men, such as coal burners, wood-choppers, teamsters, etc. This business will be pushed forward to completion rapidly. The pump of the Raymond & Ely mine has again got to work steadily, going at the usual stroke. Some of the pumping gear for the Meadow Valley pump is commencing to arrive. The work on the hoisting works is progressing with satisfaction and rapidity. Sinking on the main shaft of the American Flag continues steadily, the contractors making seven feet during the past week. In the Alps a fine body of ore is being exposed to view in the prospect work, and the usual work is going on in the mine. The Pioche shaft is having the work of sinking on the main shaft pushed, the indications as they progress being flattering. The usual work is going on in the Antelope. The owners of the Euhn & Hunt started up steam at the hoisting works during the week and are pressing forward the work of extracting ore with success. The Washington & Oreole ore is being sent to the Alps mill for reduction as fast as extracted. There have been no changes of note in mining matters, and the bullion shipments are light, but as the Raymond & Ely mill is again at work they will commence to increase.

WARD DISTRICT.

IMPROVING.—Eureka *Sentinel*, July 9: We met a friend last evening from Ward district, in White Pine county. He has a very exalted opinion of the merits of the mines of that section, and says Ward will yet turn out to be the largest camp in Eastern Nevada. The town is improving fast, there being four stores, restaurants and several saloons in full blast. The Paymaster and other leading mines of the district are developing remarkably well, none of the ore going below $40 per ton and much of it as high as $1,000. The ledges are unusually large and well defined.

WASHOE DISTRICT.

JULIA.—Gold Hill *News*, July 6: The face of the west drift on the 1600-ft level is still in soft porphyry. The main south drift on the 1600-ft level is steadily advancing, the face still in very favorable quartz and porphyry, mixed. On the 1800-ft level the main south drift is showing better and better as the drift advances. The flow of hot water on this level still continues quite strong, and considerably retards work.

OVERMAN.—Daily yield, 25 tons of ore. The ore breasts on the 900-ft level show no material change. The boh pit at the 1200-ft station is completed, and sinking the shaft will be resumed in good earnest in a day or two more.

KOSSUTH.—The main south drift on the 360-ft level is being steadily pushed ahead to the southward, following the west wall of the ledge, the face still in quartz and ore of a very favorable description. The main south drift on the 600-ft level is steadily advancing

along the east wall of the ore vein, the face in porphyry mixed with spots of quartz and clay of a very encouraging character.

SAVAGE.—The huge pumping engine is in place, and the other machinery is being placed as rapidly as such massive work can be accomplished. The old pumps and columns are being rapidly taken out of the shaft and the stations prepared to receive the new. The work is being forwarded with great energy, and if no unforseen accident prevents will probably start into full operation by the first of August.

BEST AND BELCHER.—The new exhaust fan at the mouth of the old Gould & Curry tunnel is gradually drawing off the heated air on the lower levels and cooling the mine. The temperature of the air has gradually decreased since Saturday last from 122 to 92 degrees, showing a steady and almost invaluable improvement.

AMAZON CONSOLIDATED.—Sinking the main shaft is making good progress, three shifts of men being employed. The rock in the bottom of the shaft is hard but blasts out well. The shaft is now down 342 feet.

EUROPA.—The north drift on the 600-ft level is being steadily pushed forward, following a vein of soft ledge matter enconntered in the course of the progress of the drift a few days since.

WARN.—All energy possible is displayed in sinking the shaft, which is being crowded downward at the very rapid rate of five feet per day.

DANDY.—Sinking the shaft is making good progress, the rock in the bottom being much softer, and the flow of water gradually decreasing.

BROOKS.—All work in the shaft is suspended for the present, awaiting the arrival of more powerful machinery recently ordered from San Francisco.

OPHIR.—Daily yield, 300 tons of ore, keeping the mills steadily running up to their full capacity. The ore breasts both north and south on the 1500-ft level are showing finely as usual. The north drift on the 1500-ft level is steadily advancing toward the Mexican line. About 200 tons of ore is being hoisted daily for the California mine. Everything in and about the works is in good condition and the development of the lower levels of the mine is making as rapid progress as the nature of such work will permit.

CALIFORNIA.—Daily yield, 550 tons of ore, keeping the mills running up to their full crushing capacity. The ore breasts are all looking well and yielding splendidly. The yield of bullion for the past month was better than it has ever been before and promises to be still better in the future. Sinking the C. & C. shaft is going ahead as rapidly as the strong flow of water will permit. The flow yesterday amounted to 45 inches, miners' measurement, keeping the pump running at the rate of 10½ strokes per minute, and hoisting a perfect river of water. The pumping machinery works with as much smoothness and ease at that rate of speed as when running at five strokes per minute.

SIERRA NEVADA.—Sinking the main shaft is going rapidly ahead, the bottom still in porphyry mixed with clay.

CONSOLIDATED VIRGINIA.—Daily yield, 300 tons of ore. The mine is looking well and the ore breasts are yielding good ore. The north prospecting drift on the 1700 ft level is steadily advancing, running about 50 feet east of the ledge. The drift is still intensely hot, so that but slow progress is being made. The erection of the new stamp mill is going steadily forward. The erection of the new amalgamating mill is also being pushed steadily toward completion.

JUSTICE.—The extraction of ores from the stopes between the 400 and 600-ft levels is going ahead as usual, the ore continuing of a first-class milling quality. The prospecting drifts both north and south on the 800-ft level are making good progress and are showing every appearance of opening up very handsomely. The Woodville mill is now being put in good running order and will be started upon ore from the mine in a very few days more.

BULLION.—Owing to the great heat engendered by the stoppage of the northeast drift, on the 2000-ft level of the Imperial mine, but little progress was made during the week. Sinking the main incline is making excellent progress. No change in the north drift on the 1400-ft level.

CHOLLAR-POTOSI.—Daily yield, 120 tons of ore, the assay value of which is $32 per ton. Sinking the main incline is going ahead at the rate of two and a half feet per day. Sinking the combination shaft is being pushed steadily forward. The erection of the new powerful pumping and hoisting machinery is going steadily forward.

IMPERIAL CONSOLIDATED.—Owing to the great heat, and the delay occasioned by the celebration of the Fourth of July, the progress made in sinking the north winze on the 2000 ft level has been very slow. The ore in the bottom is still very good, although not so rich as for some time past.

NORTH CONSOLIDATED VIRGINIA.—Two of the pump bobs for the shaft are about completed, ready to put in. The stations for these pumps are also about finished. The third pump station in the shaft is getting well under way. The foundations for the engine and pump bob on the surface is also steadily approaching completion.

BELCHER.—Daily yield, 400 tons of ore. The erection of the new pumping machinery is going steadily forward.

DATTON.—Day before yesterday, owing to an accident to the pumping machinery, the water rose 25 feet in the shaft, necessarily stopping all work in the bottom for the time. Yesterday afternoon, however, the damage was repaired and the water drained from the shaft ready to resume sinking.

BALE & NORCROSS.—Placing the huge coping stone, ready for the reception of the heavy pumping machinery is going rapidly forward. The old pump columns and pumps have been taken from the shaft, ready to put in the new as soon as the extraction of the other is completed.

GLASGOW.—The combination shaft has about 58 feet to yet sink to reach the 400-ft level, the point at which it is intended to open a station and start a drift to cut the ledge and tap the ore body found on the third level above. It will probably take until the first of August to accomplish this.

MEXICAN.—The north drift on the 1455-ft level is steadily advancing along the east wall of the ledge, the face in very favorable ledge matter.

YELLOW JACKET.—Sinking the east winze on the 1900-ft level is going steadily ahead, the bottom still in ledge matter, mixed with streaks of quartz and ore.

SILVER HILL.—Sinking the main incline is going ahead at the rate of 2½ feet per day.

WEST BELCHER.—The prospecting drifts on the 300-ft level are all steadily advancing, with excellent indications of soon opening up some fine pay ore.

NEVADA.—The new cross-cut from the main south drift is now in 35 feet, with quartz the whole distance, which improves, both in quality and quantity, as it is advanced upon.

CROWN POINT.—The face of the main south drift, on the 1700-ft level, is still in quartz and low grade ore.

PIOTOU.—Good progress continues to be made in sinking the winze below the main north drift. Bottom of winze in good sinking ground, with streaks and bunches of good quartz met with continually.

LADY BRYAN.—Laying the stone work for the reception of the new pumping machinery is going rapidly forward.

NIAGARA.—The last 100 feet of the main incline has been thoroughly timbered, and put in the best possible working condition. The shaft is now down 370 feet.

CALEDONIA.—The flow of water at the bottom of the shaft is still too great to permit of a resumption of work there.

TWIN PEAKS.—Grading for the large new working shaft is about completed, and sinking will be commenced to-morrow.

BALTIC CONSOLIDATED.—The ground has entirely changed since our last report. The drift is now in clay and porphyry of a very encouraging character, showing good indication of a near approach to the main ledge.

NORTH CARSON.—The new works are in the full tide of successful operation, and active development of this valuable mine is being proceeded with.

LADY WASHINGTON.—The pump arrangements are all completed and working in good style, the shaft freed from water and sinking deeper was resumed yesterday under the most favorable auspices.

CALCUTTA.—The machinery is all in place and the diamond drills are being adjusted for the purpose of commencing drilling this afternoon.

PHIL SHERIDAN.—Sinking the main shaft is going steadily forward. The flow of water is considerable.

ALTA.—The new machinery is now nearly all on the ground, and much of it already in place.

MINT.—Sinking the main shaft is making splendid progress, the rock in the bottom working well.

ROCK ISLAND.—The full force of the pumping machinery and water tanks is still employed in trying to reduce the flow of water on the 850 ft level. The flow is still quite strong.

TAHOE.—Sinking the joint combination shaft is progressing at the rate of three feet per day.

SOUTH CON. VIRGINIA.—Some fine stringers of ore are met with, and a valuable development in that line may be looked for at any time.

COSMOPOLITAN.—Ore extraction from the main tunnel drift goes ahead satisfactorily.

(Continued on Page 52.)

Darwin and its Mines.

Occasionally we discover in the San Francisco journals, says the Coso *Mining News*, some amusing descriptions of Darwin and the locality of its mines, some geographers placing us on the bordera of Death valley, while others insist that we are perched like our eagle bird on the almost inaccessible sides of the Sierras.

The Coso mining district, of which Darwin is the centre—is situated on the southwestern portion of Inyo county, in a renge of mountains called the Inyo mountains, being the southwestern extension of the White mountains. The district is bounded on the north by Lee district, on the south by Old Coso and Shepard districts, on the west by Lookout district and on the east by Cerro Gordo district—being the centre of a quadrilateral—Darwin being in the southwestern end of the Inyo renge, at an elevation of about 6,000 feet above the sea. Darwin is located about 20 miles southeast of Cerro Gordo, 15 miles south of Lee district, 12 miles west of Lookout, and 10 miles north of Old Coso. The spur of mountain on which it is located resembles Pioche in its topography and general direction. The town lies on the southern slope of the range, on an almost level plain, and contains about 300 houses with a population of 1,000 inhabitants. It is well supplied with water by pipes from a spring six miles distant. The mountains are almost barren of vegetation, but about 10 miles south the hills are well covered with timber, while the Sierras at Owens lake, 25 miles east of Darwin, there is an inexhaustible supply of splendid timber. Good wagon roads lead to the railroad, Independence, Long Pine, Lookout, Lee and Panamint, centering at Darwin.

That portion of Inyo mountains in which Darwin is situated consists of a single chain, having a general northwestern and southwestern course. It is not exactly detached from the Inyo range, but a depression of about 1,000 feet to the northward separates it appereutly, while south and west it falls gradually toward the Argus range, from which it is separated by Darwin Wash. The main bulk of this range is composed of metamorphic rocks, which contain heavy belts of crystaline and compact limestone, intersected by porphyries of various character. The lines of contact are readily discernible. The plateaus to the north and the plains to the south are composed in part of granite and lava.

In the metalliferous belt, which comprises Cerro Gordo, Lee, Lookout and Darwin, limestone is predominant. The veins occur either altogether in it, or as contact veins. The outcrops of many of the veins are bold and massive. The course of the veins is northwest and southeest, with a southweeterly dip. There are some few exceptions. Most of the veins dip from 45 to 60 degrees, except neer the surface, where irregularities are occasionally met with, which are natural to true fissure veins. The veins are of two classes: those which carry argentiferous galena ores, such as the Defiance, Cuervo, Grand, Promentorio, Bella Union, Lucky Jim, Christmas Gift, situated in Darwin, and the Union, San Felipe and others at Cerro Gordo, as also the Modoc and Minietta companies' mines at Lookout, and the mines at Lee, which, although in the same belt, are principally free milling silver lodes. Gold mostly occurrs in the southern and adjoining district of Old Coso, but traces of it exist in many of the main mines of the district. Local circumstances have been the cause that, up to the present time, but a limited amount of work has been done on the veins, hardly sufficient to realize the actual merits of many of them. Producing to develop at the same time may be judicious, but it is a slow way of developing large mines in a new district. Yet, we can truthfully assert that the mines of Darwin are a grand success, and that the future of the camp is full of hope and promise.

CHARCOAL KILNS AT WARD.—The White Pine *News* says: The Martin White company have contracted for the erection of six charcoal kilns of a capacity of 800 bushels of coal each deily. The construction of the kilns is under the immediate superintendency of Mr. Morrison, late of Wyoming Territory, who has had a life long experience in the coal business. Mr. Morrison has entered into a contract to supply the company, as soon as the kilns are completed, which will be within a month, all the charcoal that may be required to run the two furnaces, at 13 cents per bushel, at the kilne. The hauling of the coal from the kilns to the furnaces has been contracted for at two cents per bushel, thus costing the company only 15 cents per bushel for coal, delivered at the furnaces. It is said by those who have hed experience in such matters that charcoal burnt in kilns is superior for smelting purposes to thet burnt in pits or heaps, and it is certainly much freer of stones or dirt.

THE ENGINEER.

A Century of American Engineering.

The American Society of Engineers held its convention this year on the Centennial grounds, June 13th. Appropriate to the occasion Theodore G. Ellis of Hartford, Conn., vice-president of the society, read a paper giving a history of engineering in this country. The following is an abstract of the points made:

Washington was the first civil engineer of which the speaker had found any record. He gave some attention to canals, and was afterwards on a commission for improving the navigation of the Potomac. The year 1787 was a date of great interest to the profession. In that year, John Fitch, a Philadelphian, built the first steamboat, and there is every reason to believe that when he built it he was ignorant of Watt's improvements. He built the first propeller ever constructed in 1796; in 1798 he built the first steamboat for carrying passengers, and in 1799 ran it on the Delaware, between Philadelphia and Burlington. In 1804 Oliver Evans, of Philadelphia, constructed the first machine for building docks—a heavy, flat-bottom boat, with a chain and buckles to clear out the mud. It had wheels for land and a stern-wheel to propel it in the water. It seems to have been the archetype of stern-wheel boats. At this time stage coaches had not come into use. In 1807 Robert Fulton built his steamboat, and in 1811 he and Mr. Stephenson built a stern-wheel boat at Pittsburg, with which a voyage was made to New Orleans in 14 days. This was the first steamboat on Western waters.

The introduction of stage-coaches produced a demand for bridges across the larger streams, and here was a fine field for engineering talent. Among these early structures was the magnificent 340 feet span over the Schuylkill, built in 1812 and burned in 1838. Travel between New York and Philadelphia a century ago can be estimated from the advertisements in the daily prints of that day, naming the time at which a stage coach would leave for New York twice a week. On the celebration of the semi-centennial anniversary it was recorded as a matter of great wonderment that as many as 300 New Yorkers were in Philadelphia. In 1823 Champlain canal was finished and several others were in progress. About this time the evidences of progress in civil engineering began to multiply, railroads were first talked of, and there were few to prophecy what should result from their introduction. In fact, it was authoritatively stated that the claim that locomotives would some day travel 12 an hour was bringing ridicule and harm to the whole project.

The first locomotive run in this country was built in England, and was called the Lion. The first built in this country was constructed on West street, New York, in 1829. It was a four-wheeler with upright boiler, and was built for the South Carolina road. Baldwin commenced to build engines in 1833. The first iron railroad bridge consisted of three spans 55 feet long, for the Baltimore and Susquehanna railroad company, in 1846, built by James Mulholland. Iron suspension bridges were previously used in 1796, over Jacob's creek, Virginia, built by Mr. Finley. Iron bridges, however, did not come into general use until just before the civil war.

In fact, in the short space of a century American engineering has sprung from obscurity to be equal to any in the world. We have the longest bridges, with the greatest span and deepest foundations, and the only railway suspension bridge in the world; the longest railways, the best equipped, and supplied with the most comfortable conveniences. It is idle to prophecy where another century's progress may find it. The day will come when men will smile at iron bridges, when a lighter, stronger and more abundant metal will supplant iron. In aluminum is found lightness combined with strength, the only drawback to its use being the expense of extracting it from its combinations. It is not too much to expect to see bridges of a mile span made out of this metal.

Mining Engineering.

At a later session of the convention Hon. Abram S. Hewett gave a history of the progress of mining engineering and the development of the metals during the last hundred years. The first pig iron made from American ore was smelted in England in 1698. In 1702 the first furnace was built at Pembroke, Massachusetts. The total export of iron in 1717 was three tons; in 1771 it had increased to 7,525 tons. The production of coal in the year 1874, in Great Britain, amounted to 46.4 of the whole product of the world; in the United States 18.4. In the same year the production of iron in Great Britain was 45.2, and in the United States 18.1 of the whole product. This shows that the production of coal and iron in any country generally bear the same relations to each other.

The leading facts in the mining history of the country may be enumerated as follows: First, the erection in Center square, Philadelphia, of the first steam engine ever built in America. In a hundred years steam has transformed the face of the earth. Second, gold mining in the South in the early part of the century; third, the opening of the anthracite coal fields and the use of anthracite in blast furnaces; fourth, the use of raw bituminous coal in the blast furnace; fifth, the development of the copper mines in Lake Superior; sixth, the discovery of gold in California in 1848, or rather its rediscovery; seventh, the commencement of quicksilver mining in 1851; eighth, the introduction of the Bessemer steel process; ninth, the commencement of hydraulic gold mining; tenth, the commencement of iron mining in the Lake Superior region; and eleventh, the discovery of silver in the Comstock lode, which opened an era of speculation which has hardly cessed since that time.

Progress in the English Channel Tunnel.

The experimental boring at Sangatte, near near Calais, is being rapidly proceeded with, and had reached, in the beginning of the week, a depth of about 300 feet. Its object is to ascertain the thickness and condition of the cretaceous strata through which it is proposed to carry the channel tunnel. The soundings taken across the straits in autumn last, over a belt of from one to five miles wide, a little to the west of the line where the tunnel is proposed to be made, showed that no break exists in the strata, and that the dip nowhere exceeds 10 per cent. This year it is intended to make a series of soundings in English waters to settle whether an observed divergence of the chalk towards the north is due to a break or owing to dip, and another over the line of tunnel to ascertain whether a particular stratum of chalk comes there to the surface, and to take additional soundings in the portion of the chennel already examined. The general opinion among geologists is that no important flaw exists in the chalk, and that opinion Sir John Hawkshaw considers to be confirmed by the explorations of the bottom already made. There is a narrow level belt in mid-channel, whence the bottom gradually slopes upwards to either shore. It is intended to sink the boring at Sangatte, about two fathoms below the gault, and when all these preliminery operations are completed, a well will be sunk and a heading driven under the channel. With modern science and appliances, and the large experience which many similar and some almost as extensive works have given, the completion of the tunnel will involve no extraordinary difficulty. It is interesting to know that the execution of this project was seriously discussed by Napoleon and Fox, and that even then it was an old scheme.

In anticipation of this important engineering work of piercing the chalk formation under the channel, the ingenuity of the English inventor seems to have found full scope. As the Mount Cenis tunnel originated novel drills and the use of compressed air as a motor, so will very probably the channel tunnel call into play new apparatus. If the theory of the geologists is correct, the mechanical difficulties will not be anything as great as for either the Mount Cenis or St. Gothard tunnels. At present a machine has been working in an experimental way in England, applied to the face of the chalk, which seems to do its work quite effectively. The machine works like an auger, cutting off the chalk in slices, which, when broken up, are removed by means of endless bands. This machine makes a drift of seven feet in diameter, and its advance is at the rate of a yard in 15 minutes. If, then, this rate of speed could be made constant, by having two machines working from opposite ends, the channel drift would meet in about two years. It is estimated that the cost of making this seven-foot tunnel would be $2,000,000, and to increase it to the proper working size, $20,000,000 more would be required.

A NEW ENGLISH SWING BRIDGE.—The new swing-bridge over the Tyne at Newcastle, which has occupied eight years in construction, has just been completed, at a cost of about a quarter of a million, and was opened for traffic on Tuesday. The bridge is of extraordinary strength, both in the masonry and in the immense iron superstructure, has an imposing appearance and is the largest work of the kind in England. The center pier, which supports the massive swing girder, weighs 1,500 tons, and said to be unequaled. The site of the new structure is exactly that of the wooden bridge built by the Romans under Hadrian, and the old Tyne bridge, whose place it takes, was erected in 1775-79, and was removed nine years ago. The gigantic fabric which has just been finished has a total length between abutments of 530 feet, and a total width of 48 feet, the width of the roadway being 22 feet, while that of the footpaths is eight and nine feet. The bridge has six spans, resting on three piers, which have their foundations in solid rock 45 feet below the water, and correspond with those of the high level bridge; the weight of the swing girder, the length of which is 278 feet, is concentrated upon the hydraulic center press within the central pier, which contains, besides the hydraulic machinery, the boilers and engines, all of which are in duplicate.

A NEW ALPINE TUNNEL.—A company has recently been formed at Lausanne, Switzerland, to undertake the tunneling of the Simplon. It is proposed to start at Brigue, on Swiss territory, at a hight of 1,920 feet above sea level, and cut a tunnel 11.4 miles long through to Pelle, in Italy. The grade of the excavation will be on a slope of two feet in 1,000.

Oil Region of California.

A few day ago ws had an invitation from Mr. R. Paga, of the Star oil works, to visit their wells in Pico canon. They are situated about 15 milea from the San Fsrnsndo tsunel, iu ons of the wildsst and rockiest passes of the mountains, ths road for three or four miles being so crooked that ons can hardly aee 100 feet ahead, the partially dry creek winding in and out like a snake, the whole way up the gorge. The Star oil works have lately commenced to hore new wells with fine prospects, while at the sams time thsy are gradually sinking the othera to a greater depth; one well which they are now deepsning waa originally hored to a dspth of 125 feet, and there a flow of oil was struck which yielded about 10 to 20 barrels a day. Thera ars also two more wells which maks ths total amount of oil got out about 40 barrels per day. Ths company are steadily getting the wells to a lowsr strata of rock nnd expect soon to he ahls to suply the whols State with as fine illuminating oil as ths best petroleum of Pennsylvania, and lu a short time will doubtlsss bo running fully 100 barrels of refined oil a day. Day bsfors yesterday the company completed their new still fur refining, and ars already ahle to take cars of 40 harrsls of cruds oil every day. Mr. Page has lately put about $12,000 lnto ths business and they are rapidly pushing the work along. Thsre is already about a mile and a half of pips laid from ths wells dowu ths canon, and thsrs is 4,000 fest mora of pips on ths way, which will be laid as soon as it arrives. The company intend to lay ths pips all the way from ths well to the refinery, which is about nine soiles. This is a nsw thing in California and it won't he long befors the oil sxcitement will as grsat in Southsrn California as it ever was iu ths East.—*Los Angeles Republican.*

Dull Times.

W. R. Chambsrlain, who has just rsturnsd from a trip to ths sastern portion of the State, having sxtended his journey as far as Elko, informs ns that sxcessively dull timss prsvail along ths line of the road—*Reno Journal.*

Ths sama conditiou of affairs also extends to Eursks. Thsrs never was a time in ths history of the town whsu monsy was hnlf so scarce as now. The mining troubles which prsvailed here last wintsr, ths cause of which is well understood, put the ssason back at lsast 60 days. Ws all hope for bstter times during ths fall months, hut wbsthsr our hopes ars to he rsalizsd of course remains to he sesn. Ths mining interests of the district were nevsr more promising, hut for aoms unaccountahls rsason ths K. K., with an abundauos of ore in sight, is doing nothing, and ths Eureka Consolidated fails to employ its usual complemsnt of msn. Until thsss two leading mines are again in full blast, it would seem like folly to prsdiot any material changs for the bettsr in ths businsss prospects of the town. Some valuable mines ars opsning up ou Prospect mountain, hut it will be sometims yet bsfore thsy begin to tell perceptihly on the prospsrity of ths district. The truth compels us to admit, all things considsrsd, that ths outlook is anything but flattering for a livsly season. Howsvsr, if ths Eureka Con. aud K. K. ahould resums opsrations in old fashioned styls at an sarly day we might, in that douhtful svsnt, anticipate a general hrightening up of mattsrs and thiugs in this, sstion at an equally sarly period.—*Eureka Sentinel.*

Parting.—Men ssldom appsar so humans, or in a position so advantagsous to their humanity, as when thsy part. How fsw friends are there who endure a protracted separation without some abatement of warmth, or meet, hy appointment, without some precautionary anxieties, or continue together long without some accidental discontents; hut none, in any degree entitled to that character, ever part without much regret! Even the chesrful nnd social are not always exempt from those momentary perturbations with which selfishness ohills ths pulse, or oontroversy overheats it. The needls will oscillate a little from the just point of its affections, and though its polarity is never lost, it is seldom steady. Yet even ths pstulent, the irritahle, and the more generous of the resentful lose all unfriendliness as they pass away from esch other—sighing at a conversation which, perhaps, they may have mutually desired. The last ahake of the hand is sufficient to dissipate a hundred grievauces. There are then no raproaches which we oan recall beside those against ourselves.

The Richest Man in Germany.—The Bremer *Handelsblatt* has lately give to the world a most interesting piece of information. Who is the richest man in Germany? Most persons would say in reply—Rothschild, or soms long descended German Baron. In both cases the searcher for truth would he wrong. The rich man in Russia is naither bankar nor nohle, hut plain Krupp, the maker of cannon. Krupp, the gunmaker, pays more income tax than any other man in Prussia. He pays nearly 110,000 marka, whioh rsprsasnts a ysarly scale of profits exceeding 5,000,000 marks, or about $1,250,000. It is true that it is whispered in non-offioial ciroles that Krupp, the gunsmith, has a partner who shares his gains, and likswiss contributes his quota towards the paymsnt of the income tax. This mysterious individual is known unto men as the German Government, impersonated hy prince Bismarck and the Emparor William. Ths rioh man, thersfore, may not ha as wealthy as he appsars to be.

Useful Information.

Weights and Measures.

Questions are always arisiog concerning various points in weights and measures, and we print the following scale, recognized by the laws of the Unitsd States, that our rsaders may preserve it for oouvenisnt rsfersnce.

Bushel.	Pounds.	Bushel.	Pounds.
Wheat	60	Blue Grass Seed	44
Shelled Corn	56	Buckwheat	52
Corn in the ear	70	Dried Peaches	33
Rye	56	Dried Apples	24
Oats	32	Onions	57
Barley	48	Salt	65
White Beans	60	Stone Coal	80
Irish Potatoes	60	Malt	38
Sweet Potatoes	55	Bran	20
Castor Beans	46	Plastering Hair	8
Clover Seed	60	Turnips	55
Timothy Seed	45	Unslacked Lime	30
Flax Seed	56	Cornmeal	48
Hemp Seed	44	Fine Salt	55
Millet Seed	50	Hungarian Grass Seed	54
Peas	60	Ground Peas	20

Peanuts, per hushel, Africsn, 32 pounds; Tennessse, 28 pounds; Virginia, 22 pounds.

A hox 24x16 inohes, 22 inohss deep, contaius one barrsl; 16x16½ inchss, eight inches deep, contains one bushsl; 8x8½ inches, sight inohes deep, oontains one peok; 4x4 inches, four and a half inohes deep, contaius one-half peck; 4x4 inches, four-tenths of au inch deep, contains one quart.

Ths standsrd hushel of the United States contsins 2,150 4 cubic inches. "The Impsrial bushel" is about 68 cubic inches. Any box or msasurs, ths contents of which ars equal to 2,150.4 ouhic inohss, will hold a hushel of grain. In msasuring fruit, vsgetables, ooal and other suhstancss, one-fourth must he added. In othsr words, a peck msasurs five timss evsn fnll makss one hushel. The usual practics is to hsnp ths measure.

Ths standard adopted hy the United Statss is the Winohsstsr hushel, 18½ inches in diameter insids, sight inches deep, and contains 2,150 42-100 cuhic inches. It is ths legal hushsl of sach State, having no spscial statuts bushel of its own. A half hushel measars should contain 1,075 21-100 cuhic inchss.

Ths Unitsd Statss standard gallon msasures 231 cuhic inchss.

A harrel contains 40 gallons or 9,240 cuhic iuchss.

Five yards wide by 968 long contains one acrs; 10 yards wide hy 484 long oontains one acrs; 20 yards wids hy 242 loug contains ons acrs; 40 yards wids by 121 long contains one acrs; 60 feet wide by 726 long cbntains one acre; 110 fset wids by 396 long contains one acrs; 220 fsst wide hy 198 long oontaius ons acrs.

The Price of Pearls.

Of all ths suhstanoes smployed in jewslry the psarl is ths ons whose valus it is ths most difficult to determins, becauss it depsnds on so many variable conditions of size, form and color. A psarl of ths first quality should possass a fine *orient* or water. By this sxpression is meant a purs whitsnsss joiusd to a livsly luster that sparkles in the light. Thsrs are pearls, too, which, with a whits color, show a delicate rsflectiou of azurs. Thsss are ths most highly sstoemed. The second quality of a fins psarl is that it should hs perfectly sphsrical or regularly psar-shaped. There ars a great numhsr of pearls whose oolor has a ysllowish tinge. This alone is a mark of inferior quality. Ths following tahls was made hy a celehratsd Wsst End jeweler to compars the prios of pearls of the first ohoice in 1865 and '67:

	£ s.d.	£ s.d.
A pearl of 3 grains	0 17 0 to	0 19 0
" 4 "	1 5 0 "	1 12 0
" 5 "	1 17 0 "	2 7 0
" 5 "	3 5 0 "	3 15 0
" 8 "	4 12 0 "	5 14 0
" 10 "	10 2 0 "	11 2 0
" 12 "	14 2 0 "	15 1 0
" 14 "	18 2 0 "	20 8 0
" 15 "	20 3 0 "	30 5 0
" 18 "	30 5 0 "	40 4 0
" 20 "	40 5 0 "	50 8 0
" 24 "	50 10 0 "	72 12 0
" 30 "	85 18 0 "	100 17 0

Besides the individual value whioh pearls possess in common with all other procious stones, which is expressed in ths preceding tabls, thsy have anothsr very important one, which we may call *associative value*. Thus it happens that two pearls of the same form, ths same size, the same color, etc., are worth a much highsr price if sold togsther thau when sold apart. A necklace in which the pearls have heen ohosen from a great numbsr will he held at douhle the value of a neoklacs where the psarls have been picked from a smallsr numher, even when the individual value of the psarls is identical in hoth. In the first case ths harmony will he oomplets, while in the esoond oase the eye will deteot a hreak in the shadss in passing from one pearl to anothsr—*British Trade Journal.*

Cleaning Silk.—The following mode of oleaning silk garments has besn aucossfully tsstsd. The garmsnt must first be ripped and dusted. Have a lsrge fist hoard; over it sprsad an old shsst. Take half a oup ox gall, half a oup ammonia and half a pint tspid aoft water. Sponge the silk with this ou hoth sides, especially the soiled spots. Having finished aponging, roll it on a round stick liks a broom handle, hsing caraful not to have any wrinkles, Silk thus washsd and thoroughly dried, nseds no ironing and has a luster like new silk. Not only silk, hut merino, harege, or any woolsn goods, may thus he trsated with the hest resulta.

Cool Water.

A writer in the California *Agriculturist* gives the following useful hints about securing a constant supply of cool water for homs nse:

Our nights ars so cool that a small stream of water running slowly a few rods will hscome cool enough to be very refreshing all through the day.

The arrangement may he very simpls and cheap. Two ayrup barrels and forty fest of trough will do it. The barrels will cost about two dollars, and should he thoroughly scalded and washsd to take out the syrup taste. Set ons near ths watsr supply, and fill it. Set the other in the hest cool place within reach. Hop vines will grow and cover sn arbor for the barrsl very quickly. Leave ths shelter open on ths north side. Befors going to bed at night turn ths faucet at barrel No. 1, so a smnll stream will run to No. 2, at the same time draw off ths water lsft over in No. 2 to moisten the surrounding shelter.

The plan can hs modified to suit oircumstances. The water msy he located in ths milk house, but should be so arranged as to leave no permanent dampnsss about the floor. Whers there is a tank rnised from the ground a small pips can he inserted and the watsr run any desired distance, and ths larger the hody of water thoroughly cooled hy the night air the cooler it will keep through the day.

I havs practiced for ysars drawing a harrel of water out of my irrigating ditch, taking care to fill the harrsl in ths morning befors ths sun shines on ths ditch. If we evsr doubt its paying for the hother ws havs only to neglsct to fill the harrsl one day and we have no douht ahout it afterwards.

In ths citiss where ics is plsnty psrhaps a tank of cool watsr is not so nsosssary, yet I think there ars many places where its cool waters and surroundings would be welcoms. Whsre ths city water comss into ths chambers it would hs sasy to pass a small pips through ths wall and around ths house into a lowsr room provided with a tank that would havs a cooling iuflusnoe on the whols houss, and hy passing the water through a filtsr befors it sntersd ths tank it would bs improved in every respect.

Preservation of Paste with Salicylio Acid.—The souring and molding of pasts ussd by hook-hindsrs and workmsn in other trades, which, according to circumstancss, occurs in about two or three days, may he sntirsly avoided, according to ths statsmsnt of Herr P. Lang, hy the addition aud thorough mixture with ths freshly preparsd psats, of a few drops of salicylic acid. Whsn thus treated, a paste may be kept for wssks in a heated room without losing its freshness, and sven whsn it has by long standing hscome dry and tough, msy bs at oncs rendered fluid and serviceahls by trsatment with hot water. The addition of ths acid doss not, according to this author, affect the stickinsss of ths paste to any sansihls degree. The ahove itsm will, doubtlsss, prove serviceahle likswiss to all who have only occasionally to make nse of paste.—*Gewerbeblatt aus Wurttemberg.*

Good Health.

Fruits.

A writsr in the Nsw York *Tribune* constructs an essay on ths subject of fruits, from which ws oompils the following timely information. There is nothing very novel in the statements, but they will bs useful and interesting to many:

Fruits may be distinguished from vegetsbles hy the circumstauce that they oontain hardly any nitrogen or plastio matsrial, while vegotables are valuable mainly ou account of the staroh and albumsn which they yisld, and also hy the fact that, wheu ripe, trnits require no cooking to reuder them palatahle and digestible, while vegetables do. Fruits may be rsgsrded uot so much nntrisnts as agresable luxuries, for nowhers are thsy a food on which ths life of man dspends, though they are eagerly sought after in all olimats. In hot olimates thsy oocupy a higher position as foods than in temperate regions, since they do not grsatly produce heat, and yet furnish juices of an agreeshle flavor which stimulats the senss of tasts and oool the hlood. Fruits consist ssseutially of two parts, ths juices and the oellular parts in whioh ths juices are contained; the juices ars easily digsstible, hut the oells are not, and are, therefore, when possible, thrown away. All fruits contain much more fluid than solid matter, aud supply sugar, aoids, salts, and the various volatile essencss on which their flavor depends.

The grape was doubtless one of the sarliest fruits eaten by mau. It was cultivated by ths oldest oivilized Eastern nations, whence probably it was carried into Europe, as it does not grow thsre wild. It ahounded in Syria and Persia. The Romans plantsd it on tho banks of ths Rhine, and toward the close of the Roman powsr in England we find it oultivated in ssveral parts of that country by the Anglo-Saxons; aftsrward, while monastsries existed, fsw of them wsre without their vineyard. In Switzerland and other parts of Europs, ripe grapes are considsred a specific for dyspspsia, consumption and aome other complaints. Their medicinal effect is suppossd hy soms to he due to ths hi-tartrate of potash they contain. Grapes contain sugar, gum, glutinous matter, malic, citric and tartaric acids, potash and lime in proportions varying with the kind of grape and ths different conditions of soil and climate in which it is grown.

Applee contain sugar, malic acid, gum, woody fiber and watsr, together with aoms aroms on which thsir peculiar flavor depends. Though chemical analysis may show much less nutriment in apples thau in many other foods, there is much availshls nutrimsnt in them, and the vital analysis in the digestive apparatus uses thsm up closely. Peare were brought from ths Esst hy the Romans, who cultivated them with cars. Ths psar is a hardy tree, and longsr lived than even the apple. The hest varieties of the psar rank dsservedly among the most delicious of fruits. In composition ths psar does not differ very grsatly from the appls. Ths psach is a native of Persia, and was called by ths Romans Persioa. Both in ths fresh and preserved state it is a very favorite dessert. It contains sugar, gum, pectine, malio acid and water.

The orange has heen called the universal fruit of commercs, and, though the product of tropical and semi-tropical climatss, it may he had fresh in svsry region of ths world, and at almost every sesson of the year. The agreeahle sub-acid of the orange rsnders it ons of the most agreeable, cooling and wholesome of fruits, and the essential oil in ths rind is serviceable to the cook in giving flavor to msny dishss. Orange flower water, mads from the hlossoms, is a delicious anti-fehrile hevsrage, and a tea made of the lsaves of the tree is highly valued as a drink for yellow fsvsr patients. The orange pulp contains oitrio acid, malio aoid, mucilags, alhumen, sugar, citrate of lime, and watsr. The proportions of thess constituents vary with the dsgrse of ripeness of the fruit. Ths lemon hslongs to ths sams family as the oranga, and is highly valuahls for its refrigerant and anti-scorbntic propsrtiss. Its constitnents ars citrio and malic acid, gum, bitter extraction and water.

Immediate Cure for Cold in the Head.

Dr. D. Ferrisr, in the *Lancet*, suggssts a hismuth snuff for cold in tha head. Hs says: I do not know whether ths plan is absolutely original, but I am not aware of its having hssn adopted prsviously. This, howsver, is of no importance compared with the question of its efficacy.

On tne svening in question, I began to suffsr with the symptoms of cold in the hsad: irritation of ths nostrils, sneezing, watsring of the eyss, and oommencing flow of ths mucous ssorstion. Having some trisnitrate of bismuth at hand, I took repsated pinchss of it in the form of snuff, inhaling it strongly, so as to carry it well iuto ths intsrior of the nostrils. In a short time the tickling in ths nostrils and saeszing ceased, and the nsxt morning all traces of cold had complstsly disappeared.

Bismuth, alone, thersfore, proved quite succsssful, hut it is hstter in oombination with the ingrsdients in ths following formula. Bismuth hy itssif is rsthsr hsavy, and not sasily inhaled, and it is, moreover, neossary that it shonld form a coating on the mucous membraus. It is, thsrefore, advisihls to combine it with pulv. acaciæ, which rendsrs the hulk larger and ths powder more easily inhaled, while ths secrstion of ths nostrils causes the formation of an adhsrsnt mucilaginous coating, of itself a great sedatives of an irritatsd surfaces. Tue sedative sffect is grsatly strengthsned hy the addition of a small quantity of hydrochlorats of morphia, which speedily allays the fesling of irritation, and aids in putting a stop to the reflex secration of tsars.

The formula whioh I find on the whole the most suitable oombination of ths iugrsdients of the snuff is as follows: Hydroohlorate of morphia, two grains; acaoia powder, two drachms; trisnitrate of hismuth, six draohms. Of this powdsr one-quarter to one-half may be taksn as anuff in the courss of 24 hours. The inhalations ought to he commenced as soon as the symptoms of cold hegin to show thsmselvea, and should be used frequently at first, so as to kssp the interior of the nostrils constantly well coated. Esoh time the nostrils are olesrsd, auother pinoh should he taken. It may be taken in the ordinary manner from hstwesn ths thumb and forefinger, but a much more efficacious and lsss wastsful method is to use a small gutter of paper, or a "snuff spoon," placing it just withiu ths uostril and aniffing it up foroibly, so as to oarry it well within. Some of the snuff usually finds its way into the pharynx, and acts as a good topioal application thsre, should there he also pharyngeal catarrh. The powdsr csusss scarcely any perceptihls sensation. A slight smarting may occur if the mucous membrana is much irritated and inflamsd, hut it rapidly disappsars. After a few suiffs of the powdsr, a perosptible amslioration of the symptoms ensues, and in the course of a few hours, the powder hsing inhalad from time to time, all ths symptoms may hava entirely disappeared.

Toughened Glass.—This manufacturs is at present being carried ou on a small scals in Pennsylvania. By this process lamps and tumblers oau he toughened so as not to hreak. The glass, after heing run from the furnace and moldsd, instead of bsing put into the annsaling pots, is immersed in a hot bath, oonsisting of linseed oil and tallow. The hath is kspt up to about 320 deg. Ths ware after dipping is removed to a sscond bath with a temperature of 200 deg. Lsstly, tha glass goes into a water bath.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 mos.	12 mos.
Per line.....	.25	.80	$2.00	$5.00
Half inch (1 square)...	$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Four weeks are rated a month.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly se in solid type, giving in our columns one-third mor reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, July 15, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Interest in Californ ia; Avenues of Water for Hot Springs; Derricks for Hydraulic Mines; Impro ed Leaching Apparatus. 41. Underground Pumping Engines; Ventiilation of Mines by Fans; The Coming Industrial Fair, 48. American Forestry; Operations of the Choilar-Potosi Mine; Centennial District, Wyoming, 49. Gems and Precious Stones; Notices of Recent Patents, 52.

ILLUSTRATIONS.—Wall of Barait, Yellowstone River; Aaron's Leaching Apparatus, 41. The Forest and Prairie Lands of the United States, 49.

CORRESPONDENCE.—Placer County Mines; The Centennial at Philadelphia, 42.

MECHANICAL PROGRESS.—Fac-Simile Te iegraphy; Jumping the Track; Dullness in English Ship-Building; Decision on a Mechanics' Lien; Span ish Swords; Novel Skating Rink; Etching on Metels, 43.

SCIENTIFIC PROGRESS.—Insects and Plants; New Bays of Calcium; Scienc in Schools; A New Tanning Process; Photographic Maps, 43.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 44.

MINING SUMMARY from various counties in California, Nevada, Arizona, Colorado, Montana and Utah, 45 46-52.

THE ENGINEER.—A Century of American Engineering; Progress in the English Channel Tunnel; A New English Swing Bridge; A New Alpine Tunnel, 46.

USEFUL INFORMATION.—Weights and Measures; The Price of Pearls; Cleaning Silk; Cool Water; Preservation of Paste with Salicylic Acid, 47.

GOOD HEALTH.—Fruits; Immediate Cure for Cold in the Head, 47.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 52 and other pages.

MISCELLANEOUS ARTICLES.—Southern Utah; California Grapes at the Centennial, 42. Darwin and its Mines; Charcosi Kilns at Ward, 46. Oil Region of California; Dull Times; Parting; The Richest Man in Germany, 47.

NEW ADVERTISEMENTS.

Mechanics' Institute Exhibition, A. S. Hallidie, President; Antilles Mining Company—Assessment; Cast Steel Shoes and Dies, S. F.

Underground Pumping Engines.

The largest underground pumping engines extant are probably those in the Erin colliery, Westphalia. The system in use was originated by Mr. Henry Davey, and he described it at length at a recent meeting of the London society of engineers, illustrating his remarks with drawings of the steam and hydraulic engines, and also of the separate condenser as well as by working models of the machinery. The system may be thus briefly described:

In the mine (which is 1,200 feet deep), 920 feet from the surface is placed a pair of compound differential pumping engines, capable of raising 1,400 gallons per minute to the surface, at the same time supplying power through the medium of the rising column to two differential hydraulic pumping engines placed at the bottom of the mine, and employed in lifting 1,000 gallons per minute to the main engines. Steam is carried down to the main engines, from the surface, at a pressure of 70 pounds per square inch. After passing through the engines it is condensed, and a vacuum of from 24 to 26 inches of mercury is obtained by means of a separate condenser which produces at once the vacuum on the engine, and enables it to start to work against the full column. The methods of actuating the valves in the steam and hydraulic engines are peculiar. In the latter case the valves are worked without any metallic connections, by means of modification of the differential gear.

Ventilation of Mines by Fans.

The subject of ventilation of mines has attracted much more attention in Europe then in this country, and exhaustive experiments with all the different systems have been made. In England, where coal mining is so extensively carried on, the question of safety is so closely connected with that of ventilation in the mines, that no efforts have been spared to make the most perfect ventilating arrangements possible. The result of these experiments are of great interest to us here, now that our mining operations are gradually being carried on so much deeper than formerly. On the Comstock, for instance, in the opinion of many, it is only a question when they will have to stop as they go deeper, from the heat alone. This is, then, closely allied to the question of ventilation, to which, until lately, comparatively little attention has been paid. Now, however, expensive air sheets are sunk and appliances perfected to ventilate and cool the lower levels, showing that heat, ventilation and profit are intimately connected.

As regards the ventilation of mines by means of fans, some details were lately communicated to an English society of mining engineers, by Mr. John Williamson, of the Cannock and Rugely collieries, Heanerford, which are of value to us here. In the district in which the collieries are situated the furnace system of ventilation has been in vogue until recently. By experimenting on the duty effected by furnace ventilation it was found that the consumption of coal for fourteen days was seventy tons, giving 467 pounds of coal per hour, equal to nearly eighteen and a half pounds of coal per horse-power per hour. Considering the large consumption of coal and other objectionable circumstances, the Cannock and Rugely company decided to fix a Guiboldt fan and sink an air shaft of sixteen feet in diameter for an upcast. The fan has been in use since July, 1874, so that the experiments made cover an extended period of time.

There are now in the mine two downcast shafts, each twelve feet in diameter, and one upcast shaft sixteen feet in diameter. The fan is forty feet in diameter by twelve feet wide, and is fixed on the surface at a distance of fifty yards from the top of the shaft. An engine, thirty six-inch cylinder, three feet stroke, attached direct, works the fan, and there is a duplicate engine of the same size, to prevent accident. A drift was turned out of the upcast shaft at eighteen yards from the shaft top, and was continued to the fan of the same area as the shaft.

It has been found that to keep up a sufficient quantity of air circulating in the mines the fan had to make thirty-five revolutions per minute, and gave 190,000 cubic feet, with 1.5 inch water gauge, and there was 66½ effective horse-power from the engine. Then, taking the quantity of air and the water gauge, they got about 44 horse-power, or 66 per cent. of useful effect, the consumption of coal being 11 lbs per horse power per hour, and 7½ lbs less than the furnace. The fan had made 50 revolutions per minute with three and one-tenth inch water gauge. At the bottom of each downcast shaft the air was split into four sections and carried into the workings for some distance before any more splits were made, and each main split had its own return to the bottom of the upcast shaft. They got the greatest quantity of air with a low barometer pressure, and the least on a thick foggy day. But, by having a good counter and water gauge, the engineman, by slightly varying the speed, could keep a uniform quantity of air passing through the mine.

A fan of this pattern has just been started upon the Gould & Curry mine, on the Comstock, and is reported as gradually cooling the mine so as to soon permit of an entirely new departure in the ways of working lower levels on this coast. The heat on the 1700-foot level was gradually decreased from 122 to 90 degrees, on the first four days the fan was used. In view of the fact that this fan has just been introduced here, the details of its operation given herewith, will be of interest to our mining friends on the Comstock.

It is considered essential that every fan should be supplied with a duplicate engine always ready for work in case the working engine should become disabled, by accident or otherwise, because it must be borne in mind that the quantity of air passing through the mine was greatly diminished soon after the fan stopped. From experiments, it was found that an hour after the fan had been stopped the quantity of air was 71 per cent. below the quantity got while the fan was at work, and giving 86,000 cubic feet per minute at the end of two hours after the stoppage of the fan, the quantity of air was reduced 81 per cent., and at the end of three, four, five and six hours after the fan had been stopped the loss of air remained at 81 per cent., the thermometer in the intake reading 58 degrees, and in the return 68 degrees, the depth of downcast and upcast shafts being 347 yards. The quantity of air circulating in the mine after the stoppage of the fan would depend on the difference of temperature between the intake and the return airways. It should be contrived that when fans are used there should always be a large surplus of power ready for any emergency which might arise. Where that was provided, control would be obtained over the ventilation of mines, and where steam pipes were used in the upcast shaft a steam jet could be easily applied during any unforseen stoppage of the fan.

There is little doubt that if there were more fans with good reliable engines, good shafts and airways, and the air properly distributed through the mines and more attention paid to ventilation, the gases not being allowed to accumulate in large quantities, there would be fewer explosions caused by shot firing in coal mines. Mr. Williamson, who made the experiments and collected the data, questions whether there is any more effective than a properly constructed fan for sweeping the underground working and cleaning the pits of foul air. With carefully revised data these appliances can be erected at a minimum of cost, proving, in every respect, economical, and still having such a reserve of ventilating power as to meet any contingency of falls in the airways, sudden outbreaks of gas, etc. The question being raised whether the fan should be at the top or bottom of the mine, it was pointed out that it would be quite impracticable, and quite unnecessary to put it at the bottom of the shaft.

The Coming Industrial Fair.

From present indications it would seem as if the coming industrial exhibition, under the auspices of the Mechanics' Institute, would be the best ever given, and in keeping with the Centennial year. Those who are unable to go to the great international exhibition at Philadelphia, can see one proportionately as large for the territory represented. The fair will open the 8th of August. The Locating Committee are at work locating exhibitors who have applied for space. The managers inform us that more space has been applied for than at any previous exhibition.

Mr. Henry Edwards has accepted the invitation to deliver the opening oration at the opening exercises. As we stated in a previous article, preparations are being made to have more music than formerly. In addition to the two bands, a large organ has been built for exhibition, and will be placed in the art gallery.

The privilege of printing a newspaper in the pavilion has been awarded to Dewey & Co., proprietors of this journal. This will make the seventh volume of the *Daily Fair Press* printed by Dewey & Co. The experience thus gained renders them able to publish an unusually interesting and valuable journal, which forms a complete history of the industrial exhibition.

We are willing, for the convenience of those at a distance, to take charge of any ores, minerals, etc., which may be sent pre-paid to our care for exhibition. The miners of this State are able to make a very creditable exhibit in this line, with very little trouble, and we hope they will do so. We will do all in our power to further this end, and will see that which is entrusted to us is creditably displayed. The exhibition will, without doubt, be a very successful one, as the Board of Managers have had great experience in the arrangements of details, and exhibitors have come forward freely.

The plan of the main floor has been modified and some different arrangements have been made in various departments. Messrs. Gilmore and Culver occupy the respective positions which they held last year, as manager and secretary of the board, and they have been for some time laboring diligently in arranging details. Mr. Culver has been on to the Centennial exposition, and states that many exhibitors are coming on with goods. Our home industries will as usual be well represented, and no doubt the fair will be as well patronized by the public as heretofore. A spirit of emulation seems to have been inspired among exhibitors, incited perhaps by the same motives which resulted in such a magnificent display at the Centennial exposition. We shall give in the PRESS everything which will be of interest to our special class of readers in connection with the exhibition, taking particular care to describe in detail those matters of value to them.

HISTORY OF THE COMSTOCK MINES.—Next week we expect to give No. 1 of a series of articles embracing the early history of the Comstock mines, by an able and well-known writer on mining subjects. The facts have been collated with a good degree of careful and successful research. The series will prove not only of particular interest to residents of Nevada, but will contain much of information interesting to the general reader, concerning this world renowned mining district.

A DISASTROUS FIRE.—The fire in the Sierras near the upper mill of Mackey & Fair, on the 6th inst., destroyed 8,000 cords of wood, several millions of feet of lumber in the log, 2,000 acres of pine forest, etc. Neither the mill or lumber flume were burned, but the damages done will foot up not less than $100,000. It was supposed to be the work of an incendiary.

LIST OF PATENTS.—For some unaccountable reason our usual list of patents did not come to hand from the Patent Office this week. We shall publish both lists next week.

MR. HENRY G. HANKS, the well known assayer and mineralogist of this city, delivered an interesting lecture on the "Metric System" before the Photographic Society this week.

Foundry Work.

The Risdon Iron Works.

These works are one of the three largest foundries of the city, employing from 250 to 350 men according to requirements. The works cover a space about 300x300 feet. They have all the necessary appliances for turning out any style or size of machinery, but make a specialty of mining and marine work. They are able to take a contract for building steamers, etc., and turn them out ready for sea. Among some of the work of this character may be mentioned the revenue cutter *Oliver Wolcott*, the *Newport*, *Arcata*, etc., with surface condensing engines. The *Los Angeles* and *Ventura*, were fitted with compound engines. Of hydraulic machinery also a specialty is made, for pumping, hoisting, etc. The hoists in the Palace hotel were made on this principle by these works, and are fine examples of hydraulic engineering. Mr. Moore the superintendent of the Risdon, is owner of the patent for this coast of the direct acting engines with the Davy differential valve gear, now so largely in use. All of the large engines lately built for the Comstock are made on this principle.

The largest machinery in the mining line made at these works is that of the Belcher pumping works, which are now being put up at the mine. They are capable of pumping 750 gallons per minute from a depth of 3,000 feet. When it was found that the old pumping machinery would not drain the shaft it was proposed that the new air shaft, completed to the 1000-foot level should be made a drain shaft as well. The mine was already drained to the depth of the 1600-foot level so very powerful pumps were required as at that point the shaft when sunk further must drain not only the Belcher but the Crown Point mine, which latter was to pay a proportion of the cost. The plans were devised by Mr. W. H. Patton. The engine is known as the Imperial beam compound direct acting pumping engine, and has an initial cylinder 30 inches in diameter and a 10-foot six-inch stroke. The expansion cylinder is 62 inches in diameter and the piston an eight-foot stroke. The expansion is set on a solid sole-plate, secured to the foundations immediately over the rear end of the pumping beam. This beam is of cast-iron trussed with wrought-iron. It is 32 feet six inches in length and 11 feet deep, between centers. The main center is 20 inches in diameter in the middle and 16 inches in the journal. The piston connects direct with the beam by a 10 inch pin, avoiding all superfluous and extra gearing. The connecting pin with the pump rod is 11 inches in diameter, and the engine is controlled by the Davy differential valve gear. The condenser and air pump are entirely segregated from the pumping engine, work independent and are also controlled by the Davy gear.

The boilers are six in number, each 54 inches in diameter, 16 feet in length and of the tubular make. The stone foundations upon which the whole is placed are built in pits blasted from the bed-rock, and will contain over 2,000 perch of solid stone. The plunger pumps will be placed at distances of 200 feet apart in the shaft. A single line of 14-inch pumps will extend from the surface to the bottom of the shaft, capable of throwing, with the engine running at a rate of 10 strokes per minute, 30,000 gallons of water per hour. When the engine starts up it will probably begin pumping from the 1700-foot level. It will begin running about the 1st of August.

THE BONANZA.—A street rumor has been in circulation that Robert Barton, the well known mining engineer, had stated that the 1700-foot drift of the Consolidated Virginia mine was as barren as Mount Davidson. The reporter of a city cotemporary interviewed Mr. Barton on the subject, who said: "As to the correctness of these reports, I simply say that they are false from beginning to end, for I had free access to all parts of both the Consolidated Virginia and California mines, the 1700-foot level inclnded. And as to the correctness of anything I may have said about the 1700-foot drift, I refer to the official reports at the office, where anyone can learn that this drift is not within 50 feet of the ore vein, and of course is as barren as any drift which would be run into Mount Davidson. With regard to the future prospects of the 1700-foot level drift of the Consolidated Virginia, I do not hesitate to renew my former assertion, and am more positive now than ever that the 1700-foot level of the Consolidated Virginia, when fully developed, will show more wealth than the whole Comstock can show to-day; but it will take a little time to prove this—perhaps a few months.

IN NEVADA.—"Our own correspondent," Mr. A. C. Knox, who has been associated with the business department of this paper since 1865, will soon visit Virginia City and other parts of Nevada.

ALPINE COUNTY MINES.—We shall commence next week a series of articles on the mines and resources of Alpine county, from the pen of one who is well qualified to write about them.

IT IS reported that the strike of an ore body has been made in the Sutro tunnel, but nothing authentic has yet been made known.

American Forestry.

We printed not long ago a note of the organization of a national society for the promotion of forestry. The objects of the society, as announced, were the collection of accurate statistics concerning forest planting and growth, and the promotion of every effort to encourage the planting and preservation of the forests. The society is apparently in full sympathy with the movement in progress in this State and which we trust will not weary until our hills are crowned and our valleys shaded with thrifty forests.

We print on this page a map of the United States drawn with especial reference to the forest areas. The regions in which the different classes of forest trees grow are marked according to the explanation on the margin of the engraving.

As one looks at the immense areas in which trees flourish, it appears clearly that there is no lack of natural adaptation to the growth of trees. More than this, one must take into consideration the wide stretches of prairie lands on which the trees should flourish to the comfort and profit of the husbandman. We trust the National association of forestry will accomplish much good in developing the timber and shade producing resources.

As we call this subject to mind and show how wide a timber lot pertains to Uncle Sam's farm, we should also call attention to the

Rapid Destruction

Which is being made of the valuable possession.

Some of the figures given to show the enormous annual consumption of wood are startling. For example: The locomotives on the railroads of the United States annually consume as fuel as much wood as would represent 25 years' growth on 350,000 acres. In order to supply the railroad ties used annually upon the roads now in operation, the timber of 30 years' growth must be removed from 68,000 acres of the best natural wood land. The telegraph lines now in operation require for repairs that at least 250,000 trees be cut annually. Even the manufacture of such insignificant things as shoe pegs and matches requires in the aggregate a great deal of lumber, amounting in the former case to 100,000 cords of white birch, and in the latter to 230,000 cubic feet of the best pine. An estimate has been made that "during the 10 years between 1850 and 1860, 30,000,000 of acres of forest covered land were cleared in the United States for agricultural purposes, or 10,000 acres a day for each working day during that time." These are some of the least thought-of drains upon our timber supply, and yet how large they are. If we but bring to the estimate the enormous consumption of wood for fuel and timber for building it will be difficult for the mind to grasp the annual reduction of the tree census of the country.

THE FOREST AND PRAIRIE LANDS OF THE UNITED STATES.

The Beneficent Effects of Forests.

Forest culture has progressed so far in some parts of the world that we are able in some degree to appreciate the influence of the forests upon the climate and productiveness of the regions in which they prevail. We desire to present a few facts in this connection. Let us instance first the value of the shelter against injurious winds. According to M. Becquerel, the physicist, who had investigated this subject, perhaps more than any other, in the valley of the Rhone, it is found that a simple hedge, six feet high, is sufficient protection for a distance of about 50 feet. The clearing of the Appennines is thought to have considerably affected the climate of the river Po, in Italy. Mr. Geo. P. Marsh, quoting from an Italian publication, says: "In consequence of the felling of the woods on the Appennines, the Sirocco prevails greatly on the right bank of the Po; in the Parmesan territory, and in Lombardy, it injures the harvests and the vineyards; sometimes even ruining the crops of the season. To the same cause we may ascribe the meteorological changes in the precincts of Modena and Reggio. In the communes of the districts where formerly straw roofs resisted the force of the wind, tiles are now hardly sufficient; in others, where tiles formerly answered for roofs, large slabs of stone are now insufficient; and in many neighboring communes the grapes and the grain are often swept off by the blasts of the south and southwest winds." There are other instances on record where the planting of numerous shelter-belts has relieved the inhabitants of southern Europe from the ravages of the dreaded Sirocco. Mr. Marsh gives several instances much in point. He says: "The following well attested instance of a local change of climate is probably to be referred to the influence of the forest as a shelter from the cold winds. To supply the extraordinary demand for Italian iron occasioned by the explosion of English iron during the time of Napoleon I, the furnaces of the valley of Bergamo were stimulated to greater activity. The ordinary production of charcoal not sufficing to feed the furnaces and forges, the woods were felled, the copses cut before their time and the whole economy of the forest deranged. At Piazzatore there was such a devastation of the woods and consequently such an increased severity of the climate that maize no longer ripened. An association, formed for the purpose, effected the restoration of the forests and maize flourishes again in the fields of Piazzatore." Similar effects have resulted from plantations made in Belgium.

In an article published in the *Revue des Deux Mondes*, quoted by the same authority as before, it is said: "A spectator placed on the famous bell-tower of the cathedral of Antwerp saw, not long since, on the opposite side of the Scheldt only a vast desert plain; now he sees a forest the limits of which are confounded with the horizon. Let him enter within its shade. The supposed forest is but a system of regular rows of trees, the oldest of which is not 40 years of age. These plantations have ameliorated the climate which had doomed to sterility the soil where they are planted. While the tempest is violently agitating their tree-tops, the air a little below is still, and barren sands have been transformed under their protection into the most fertile fields."

In certain districts of Sweden where the woods have been cut away the spring comes about two week later than formerly. There are numerous instances on record where the climate of a place has been materially changed by clearing it of trees. Spring is thus retarded and earlier frosts appear in autumn.

Trees in California.

We expect to see, when the National society compiles its statistics, that California stands foremost among the States which deserve praise for tree planting. During the last few years there has been a widespread spirit of tree planting, and seedlings have been put in by the million. We are introducing new trees and have found many which are admirably suited to our climate and soils. We have experienced also the beneficial effects of shelter. In some of our southern counties rows of trees hold back the ocean winds and render the protected orchards doubly fruitful. Our market gardeners work behind a wind-break of their own planting and secure very early growths of vegetation. By the beauty of trees many a barren waste has been transformed into a grove and many a hot highway has been made an avenue of grateful shade. But still there is room for wider planting and we look with real favor upon any movement which will promote the good work. According to the census of 1870 the amount of woodland in the United States was about 380,000,000 acres, and the whole area of the country, improved and unimproved, was 2,311,544,959 acres. Of all the States, shown in our map, California has the smallest proportion of woodland to her whole acreage; while some States have a percentage as high as 50 and 60, California has but five. Thus it appears that there is good call for our activity in tree planting, and we trust that each recurring year will see more and more of our waste land turned to profit by the planting of a salutary and valuable growth of trees.

Operations of the Chollar-Potosi Mine.

The annual meeting of the Chollar-Potosi mining company was held on the 10th inst., and all the old officers were re-elected. The reports of officers for the fiscal year were submitted. The following is a synopsis of the report of Isaac L. Regna, Superintendent of the mine, which is among the prominent ones on the Comstock.

At beginning of fiscal year, June 1, 1875, there was on hand 1,415 tons of ore; extracted during the year ending June 1, 1876, 19,817 tons. Of this amount 17,728 tons was milled, leaving a balance of 3,504 tons on hand. This ore yielded on an average $18.03 per ton. Milling the ore cost $11.83, and cost of extraction was $4.20, which left a profit of $2.00 a ton on all crushed. The ore was taken exclusively from the "old mine." During the year prospecting has been carried on in that particular section which has developed several ore bodies, a part of the ore of which only has been taken out; and there remains in sight in the several stopes more ore than has been exposed at any time during three years past, and indications point that more ore of greater value will be found by further prospecting. In the "new mine" operations have been conducted on an extensive scale. Three hundred feet have been added to the depth of the main incline; the 1300-foot level has been opened, and this, as also the sixth and seventh stations, has been thoroughly prospected—to do which some 3,360 feet of drifting was done. At date of report the main incline was being carried down, the sinking to be continued till a sufficient depth for another station should be reached, indications on the sixth, seventh and eighth stations indicating that ore bodies may lie deeper. The machinery was in good order and of a capacity to work the mine 700 feet deeper than present workings.

The report of W. E. Deau may be summarized as follows: The total receipts in the year were $744,556 04 of which $312,415.36 was from bullion, $280,315 from assessments 8 and 9, and $2,062.50 from rents, $2,000 from real estate, and $3,795 76 from the superintendent. At the beginning of the year there was $68,036-85 cash on hand, but at the close there was an overdraft of $75,881.57 against the company. The disbursements absorbed all the receipts; but excepting the overdraft, the company is out of debt. The main items of expenditures were $164,353.75 for labor, $24,095.88 for wood, $210,186 for working ore, and $232,947.96 for for the company's proportion of expenditure on the joint Chollar-Norcross-Savage shaft.

Gold leaf is cut by placing it on a flat, clean leather pad, pressing it very gently and sawing with a perfectly straight-edged knife or split cane. Dutch metal may be cut between paper by close shearing scissors, with such long blades that each cut is made with one motion.

Centennial District, Wyoming.

Some weeks since a dispatch appeared in a number of newspapers, setting forth the wonderful richness of the lately discovered Centennial mine, in Wyoming Territory. The statements were so evidently exaggerated that few mining men gave any credence to it, and it did not even raise any excitement among that class of peripatetic prospectors who are always on the lookout for new districts or discoveries. There is, however, such a mine as the Centennial, and it is situated in Centennial district, Carihou county, Wyoming. The dispatch was originated by a newspaper in that part of the country, the editor of which was endeavoring to turn aside the rush for the Black hills, and get some of the miners to prospect the mountains of Centennial district.

We had an opportunity this week of conversing with Mr. J. P. Lambing, the superintendent of the Centennial mining company, who was in this city for the purpose of purchasing drills and concentrating and crushing machinery for the company. He is an old miner, but does not appear to be at all an excitable man, and gave us some facts about his part of the country which will be found of interest. Centennial district is a new one, the discovery having been made about a year ago last December. It is about 30 miles from Laramie City, to which there is a good road and a daily stage. There is plenty of wood and water in the district, and every facility for working that could be desired. The altitude is about 8,270 feet above sea level. The snow does not give much trouble in the winter, but the winds are very heavy. The mill belonging to the company is in a sheltered position at the foot of a mountain, but as a general thing the country is very windy indeed.

Labor is low, and facilities for mining, as far as expense is concerned, are very favorable. At present wood is delivered at the mill for $1.75 per cord. Miners' wages are from $2 to $2.50 per day in greenbacks. There are now from 300 to 500 men in the district, and quite a little town has sprung up. A sawmill has just been started, and lumber sells for $20 per thousand. Nearly all the miners there now are prospecting. The country is hard to prospect, as the ledges are all "blind." The usual method of digging trenches or "cuts" is resorted to to find the ledges. The country is in a micaceous slate formation, and the ledges generally run north and south, although the Centennial — the representative lode — runs northwest and southeast. The mineral belt runs through the head of the Douglas creek, where placer diggings have been long known, but where it is too high and cold for a long mining season.

Since the discovery of the district it has developed slowly. The Centennial company have a ten stamp mill which is crushing about eight tons a day. Since work was commenced the rock has yielded an average of $19 per ton. The gold runs from 906 to 913 fine. Our informant tells us that since last May, thirteen other ledges have been discovered. The gold is extremely fine but the ore is perfectly free. The mill is now run by steam, but water power will soon be used. Either of the three forks of the Laramie river will furnish an abundance of water for that purpose. It is thought that for $3,000 will bring in 700 horse power, including the covering for this ditch to keep it from freezing in winter. The mill could have been run all last winter, but the small creek beside which it is situated froze up. The ledge of the Centennial mine is about three feet wide, which is as large as any in the camp. At the time the dispatches were published, which we refer to above, a small stringer ran into the main lead from which assays as high as $47,000 per ton were obtained. There was very little of this class of ore, however, as any miner may suppose.

Mercury is made to adhere to any metal by putting a very little sodium with the mercury, the hundredth part by weight is ample. The sodium mercury may, if necessary, be washed off by fresh, pure mercury, which continues to adhere.

DEETKEN'S

ROASTING FURNACE,

For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 6 to 50 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adapted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

G. F. DEETKEN,

Consulting Metallurgist, Grass Valley, Cal,

Furnace can be seen on application for permit, at Grass Valley.

Buffalo Excelsior Pony Planer & Matcher

Patented Mar. 30th, 1875.

Best of its kind in use. Price, complete, $275. Also, small Pony Planers and Planing Machine knives, which are recommended as superior and extra in quality. 100 Scroll work designs free on receipt of stamp. For circulars giving detailed information, address

WHELPLEY & STORER'S

Desulphurizing Furnaces, Crushers and Pulverizers for

GOLD, SILVER and COPPER ORES.

State, County and single rights for sale at reduced rates. Machines furnished at short notice.

LEVI R. GREENE, Trustee,

69 Kilby Street, Boston, Mass.

THE O'HARRA

CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
1500 lbs of salt at 1½c	22.50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

WHTE PINE DISTRICT.

THE FURNACE. — White Pine *News*, June 29: The greatest ornament Hamilton has is the Panther furnace, which has so long stood idle, but is now in full blast, under the management of Harry Strout, who has everything in perfect running order. James Montgomery is chief engineer. The furnace produces an average of six bars per hour—this from a 20 ton furnace. Mr. Paul, who does the assaying, finds that the slag contains but $1.21 per ton and one and a half per cent in lead. Mr. Strout expects to continue this run from 40 to 60 days. When it is taken into consideration that there are hundreds in and around Hamton who are indirectly benefited by the running of this furnace, the pleasure of its being successfully started is great with all. This universal benefit that would accrue to all grades of business was the cause of the organization of the smelting company last summer, and if the furnace successfully runs for three or four months, no subscriber to the Hamilton smelting company will have cause to rue it, for the furnace, in all probability, would not have been running to-day had not the merits of our base mines been brought to light by the operations last summer.

Arizona.

CEDAR VALLEY DISTRICT ITEMS.—Wallapai *Enterprise*, June 27: From Cedar Valley district we learn that P. H. Tompkins has just finished working, at the steam arastra in Echo canon, a lot of seven tons of ore from the Gunsight mine, of which he owns the control. The ore pulped $300 silver per ton, and the clean-up gave him 1,798 ounces of bullion, valued at $1,900. This is really an excellent yield. The Messrs. Buhle are running a tunnel to tap the Brooks mine. The tunnel is now in about 60 feet, and in 100 feet more they will tap their mine about 150 feet below the surface.

CERBAT.—Messrs. Barry & Williscraft have for some time past been hunting for water in sufficient quantity to run a mill in Cerbat, and we are glad to learn that they have succeeded and that a five or ten-stamp mill will soon be on the way out.

MAYNARD DISTRICT.—S. Shoultes, of the American Flag mine, in Maynard district, was in town during the fore part of the week. This mine has a shaft 125 feet deep, and shows a body of exceedingly rich ore four feet in width. The last lot of ore from this mine, worked in the Mineral Park mill, yielded $1,032 per ton in silver. It is one of the richest mines in the county.

WALLAPAI DISTRICT.—The Metallic Accident, in Wallapai district, is looking better than ever. The shaft is now down about 70 feet. There are several men at work on the mine.

Colorado.

BULLION SHIPMENTS.—Colorado *Miner*, July 3: The shipments of bullion from the Judd & Crosby works, for the week ending June 30th, amounted to $6,426.34.

ZINC.—A series of experiments is now being conducted here and in the East with the object of ascertaining the best method of utilizing the zinc in a large class of our ores. When this is ascertained, capitalists now interested in works for the treatment of zinc ores, will at once erect works in the valley, and render useful and profitable a metal which has hitherto been only a detriment to mill men. A gentlemen of large experience in handling the ores of this district, has agreed to furnish 4,000 tons per annum, carrying over 40 per cent. zinc and from 20 to 200 ounces in silver.

PARK COUNTY.—A large and rich body of ore was struck in the lower tunnel of the London last week. The ore yields at the rate of six ounces per ton in gold, 50 in silver, and 25 per cent. of lead.

JEFFERSON COUNTY.—The Golden Works turned out between Monday morning and Saturday night of last week, $11,000 in bullion. Ore is coming into these works in large quantities from all the mining districts, especially from Georgetown district, and also from the Snake River district across the range.

Idaho.

TROUBLE IN OWYHEE.—Idaho *Statesman*, July 4: Mr. Charles S. Peck, of Owyhee, owner of the Bella Peck mine, arrived here last Saturday, and made us a pleasant call. Mr. Peck reports that his mine is paying well, and still sustains the reputation of being one of the best mines in that camp. He says the day he left a speck of trouble arose in the management of the Golden Chariot mine. The hands, about 150 in number, had not been paid for the months of May and June. Mr. Baldwin, the superintendent, had promised to pay on the close of June for the month of May, leaving the month of June unpaid. This would have been satisfactory had he done so. He had reported to his company in San Francisco that his proceeds for that month would amount to about $25,000, but instead, it amounted to only about $10,000. This amount Baldwin turned over to C. W. Moore, on an old indebtedness, and, of course, had nothing to pay the hands. The first of July and the glorious Centennial Fourth was just at hand, and the hoarding houses would be shut down and all hills cut off. This course excited the miners, and, after holding a meeting, they marched down in force and took Mr. Baldwin up to Fairview, where he is kept as a hostage to secure the payment of the money. The affair creates a little excitement, but they do not apprehend any violence to Baldwin. Mr. Peck says the Chariot mine is paying well and will meet all working expenses, and some more, but miners have had so many set-backs, and in many cases 10 and 12 months' pay is in arrears, that they will not allow the bullion to be paid on old debts or sent below without being paid for their labor. From Mr. Peck's version of this matter, we believe that public sympathy is and will be with the miners.

STONDARD LEDGE.—Owyhee *Avalanche*, July 8: The fortunate owners of this ledge have undoubtedly got a bonanza on their hands. They had some of the rock crushed recently and it turned out about $72 to the ton. Everybody acquainted with the mine knows that there is abundance of this kind of rock in sight, much of which will turn out still better. It is one of the best claims in the Wagontown district, and the boys who are interested in it have demonstrated their confidence in its paying capacity by pulling off their coats, going to work and developing the mine in a business like and practical manner. Messrs. T. Regan, Johnny Springer and the Stoddards left here this week well stocked with supplies, and will spend the balance of the season working on their ledge and taking out rock.

Montana.

MINING ITEMS.—Butte *Miner*, June 27: A full supply of water still enables the placer miners to continue work night and day upon the claims below town, and heavy returns from this year's work are expected by all engaged in this branch of mining. If in the other camps throughout the Territory as much success has been met with as in this one, there will be no scarcity of gold at the end of the season. On Davis' arastra they have commenced amalgamating the rock crushed, but as it was of an extremely low grade ore, intended simply to fill up interstices and test the working power of the machinery, not much in the shape of bullion is expected from this run. The ore secured by Mr. Davis, which is now being crushed, is a medium grade, and will probably average about $120 to the ton. At the Parrot mine no diminution in the quantity of ore daily raised is perceptible. A force is still at work and the quality of the ore is excellent. The last lot sacked—over 40 tons—sampled 52 per cent. copper. There is a large amount now on hand at the mine, the numerous shipments apparently making no difference in the looks of the several bins. Fourteen tons of ore were taken away to-day for a market at Baltimore. The progress made on Olin's concentrating works has been greatly retarded and work has gone forward quite slow, owing to unavoidable circumstances, but it is expected that before another week the dressing of ores will have commenced. There is now on the dumps at the various mines large quantities of ore averaging 20 per cent. copper, which will give the Olin works sufficient to do for the balance of the season, without taking any additional from the mines. At the Park mine the rich streak of ore found a short time since still holds out, and they are hoisting about a ton and a half per day. Some 30 tons are in the bins awaiting the arrival of sacks, and over 70 tons sacked and ready for shipment, which will be sent off as soon as transportation arrives.

CABLE CITY.—Cor. *New Northwest*, June 30: Messrs. Kohrs & Cameron got water into their ditch on the 21st inst., and started the Little Giant in the placer mine on Cable side on the 22d, nearly 20 days later than usual. They are working a breast of gravel over 20 feet high, and it looks splendidly; will work about seven men this summer. Wages this year only $4 per day. Messrs Cameron & Kelley are in about 100 feet on lower level on Pyrenees, and have about 20 feet to run to strike quartz. The road, on account of the late snow storms, is still impassible with heavy loads. Messrs. Lacaff & Brown made a good strike last week in quartz on the Georgetown side, near Pyrenees, and made a location. They have taken out some three tons of excellent rock and a few fine specimens.

Utah.

RUSH VALLEY.—Cor. Salt Lake *Tribune*, July 9: The past week has been one of unusual activity in and around Rush Valley mining district. A few fine strikes and discoveries have been made upon old locations. The most promising of which is to be seen on the Globe mining location, owned by Bennett & Tornetten, where they have opened a five-foot vein with two and a half feet of solid carbonate of lead ore, encased in a lime foot and quartzite hanging walls. It has the appearance of a big thing. Rush valley has got to rushing out ores faster. Messrs. Longmaid & Co. have found it necessary to extend and enlarge the capacity of their furnaces and machinery, and this week they will have upon the grounds at their present furnace, two large 40-horse power engines and boilers, to be set in position and at work immediately.

TINTIC DISTRICT.—This district is still right side up, and quietly adding its quota to the mineral productions of our Territory, but there is still plenty of room for enterprise and capital in the district. Around Diamond City things seem loudest, and quite a number of mines and good prospects are being worked. The Wendigo company are sinking a shaft on the Joe Bowers lode, calculating to run it down some 700 feet. Ore is occasionally taken from the mine, assaying from $2,000 to $3,000 per ton. We trust its enterprising proprietor may strike a big bonanza of that grade of ore. As a whole, the district is quiet; it needs and is worthy of more attention than it appears to at present receive, but for all that, it is producing largely and is shipping ores, silver bullion, copper matte, charcoal and very large quantities of iron ores for fluxing purposes. For the capital invested and the number of men working, the district is doing certainly as well and probably better than any other mining district in Utah in the production of hard facts in the shape of money-producing products.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANKS.]

H. Almandine. Carbuncle Essonite, Precious or Oriental Garnet, Pyrope.

The above varieties belong to the garnet family, members of which take a variety of forms and composition. As other varieties do not rank as gems, no description of them will be given.

Garnets are silicates of different bases, as alumina, lime, magnesia, iron, manganese, etc.

The almandine or almandite is an iron-alumina garnet, of which the following analysis is from an average specimen. The composition varies: Silica=36.1; alumina=20.6; protoxide of iron=43.3. Total, 100.0. This is the precious or oriental garnet of the present day, and the carbuncnlus of Pliny, from which the common name of carbuncle is derived.

Pyrope, sometimes called Bohemian garnet, is a silicate of alumina with various protoxide bases. The following is an analysis selected from a number of others:

Silica, 42.08; alumina, 20.00; sesquioxide of iron, 1.51; sesqui oxide chromium, 3.01; protoxide of iron, 9.09; oxide manganese, .32; magnesia, 10.20; lime, 1.99.

This gem, a blood red, transparent conchoidal. Luster vitreous, streak white. Hardness, 6.5-7; specific gravity, 3.69—3.8. Found in Bohemia. Fine specimens are brought to this country from Arizona and New Mexico, where they occur in abundance. Until this discovery was made Bohemia alone furnished them to commerce. Quite a quantity of these beautiful stones were sent to M. E. Costa of Paris to be cut.

The pyrope, when fine, is often mistaken for the ruby, and when well cut is hard to distinguish from that rare gem; the test of hardness and specific gravity, however, will serve to distinguish the two.

The essonite is a lime garnet. Another name given to it is "cinnamon-stone," a cinnamon colored variety from Ceylon and India. The common varieties are called grossularite.

In composition it is a silicate, mainly of lime and alumina. When green it owes its color to the oxide of chromium. An amber colored variety, which occurs in Piedmont, is called from its color, succinite.

The general composition of this variety may be seen from the following average analysis: Silica 40.1, alumina 22.7, lime 37.2=100.

It is curious to trace out the origin of the names of the varieties of the gems.

Garnet is derived from the pomegranate, the seeds of which the garnets were thought to resemble.

Carbuncle is literally "incandescent coal."

Pyrope is named from two Greek words, signifying "fire color."

The almandine garnet takes its name, (*Almandic carbunculus*), from its having been cut and polished at Albanda, in Pliny's time. Albanda was a town in Caria, Asia Minor, named from a deity, Albandus, worshiped there.

Pliny writes of drinking cups of the capacity of a pint being cut from a single carbuncle.

The garnet is common in mica schist, gneiss granite, chlorite schist and other rocks. It is also found massive, forming rock masses of considerable magnitude. It is sometimes found in serpentine and lava.

There are numerous localities of the common varieties of the garnet, both in the United States and Europe. On the Pacific coast, besides the localities already mentioned the following are known: Very fine crystals of almandine are brought from British Columbia. Fine crystals of essonite occur in the Inyo mountains, near San Carlos, Inyo county, associated with dathotite. Grossularite is abundant in the southern counties of the State, some of the crystals resemble cassitrite, (oxide of tin), and have often been mistaken for that mineral by the Cornish miners.

The garnet crystalizes in the isometric system.

The pyrope is generally, if not always, found in rolled amorphous masses from the finest sand to pieces the size of a pigeon's egg.

The garnet can be positively electrified by friction; some varieties possess polarity.

Before the blowpipe almandine and common garnet fuses easily to a magnetic globule. Pyrope fuses with difficulty.

Although the garnet is considered as a gem, yet it never is much sought for in jewelry, being too common to demand a high price; yet garnet sets have at times been fashionable, at which times their value has greatly increased.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency the following are worthy of mention:

AUGER HANDLE.—Geo. L. Gibson, Reno, Nev. This invention relates to an improved handle for augers and boring bits, and provides a simple and effective arrangement, by which the handle is rendered capable of holding augers and bits of different sizes.

STEP LADDER.—Edward A. Stockton, S. F. In constructing this improved step ladder, the inventor uses three round bars or rods to form each upright side bar or step support. These rods are passed through holes properly arranged in the ends of the steps and when the ends of all three bars are drawn together at top and bottom and secured by suitable strong fastenings so as to form them into a triple truss. A side support for the steps of step ladders has heretofore been made of two straight bars which passed through holes in the ends of the steps, but they did not form a truss, and a triple truss has been formed by partially splitting a board in three parts and spreading the parts in the form of a truss, but this support was secured against the ends of the steps and was liable to be wrenched off by frequent strains upon the ladder. The inventor also provides an improved and convenient hinged bar for retaining the ladder brace at the proper spread and also an improved system of bracing the ladder brace.

BALING PRESS.—Jacob Price, San Leandro, Alameda county. In this patent are comprised certain improvements in that class of upright baling presses in which the follower moves from the bottom upwards, so as to compress the substance to be baled to the upper ends of the press. The first improvement relates to a novel manner of applying the toggle levers and an operating screw for raising the follower; also to improvements in the construction of the follower. The second relates to a very simple and effective locking device for fastening the side doors of the press in their closed position, so that they will sustain the inside pressure and yet be easily released when it is desired to open the doors to remove the bale. The third improvement comprises a fastening for retaining the hinged top of the press in its closed position.

GRAIN COOLER.—J. H. DeForce, H. H. Hurd and George Simpson, Redwood City, San Mateo county, Cal. This is an improved flour cooling attachment for grist mills. The improvement consists in forcing one or more currents of fresh air into the flour bolts or bolt chest, in which the flour is bolted, thus not only cooling the flour, but serving also to prevent the interstices of the bolt cloth from becoming clogged. By cooling the flour in the bolt or chest it is prevented from sweating and packing in the bolt, and is caused to bolt with much greater freedom than when it is not. The flour is cooled by this process without additional machinery, except the blower and air pipe or tube, which become a stationary part of the mill.

PAVEMENT.—John M. Snook, San Francisco. This is an improvement on that class of pavements, walks, etc., in which concrete, cement, etc., harden by exposure to the air so as to form an artificial stone surface. The object of the invention is to provide such a construction of the foundation, upon which the artificial stone is laid, that the material can be spread in a continuous body so as to present the appearance of being made in separate blocks or figures, and so that in case of contraction, upheaval or settling of the surface, any fractures will be in uniform straight or regular lines, thus preserving the appearance of the surface.

ARTIFICIAL STONE.—Leathers & Chappelet, Oakland. These gentlemen have received lately two patents. One of these for a novel combination of materials for producing an artificial stone of superior strength and durability. The other relates to a novel process and apparatus by which they are able to make artificial stone in imitation of mosaics without increasing the expenses of manufacture and with but little additional manipulation or handling, other than is required in the manufacture of the plain artificial stone.

CURRENT CHANGER FOR TELEGRAPHIC PURPOSES.—Stephen D. Field, S. F. Mr. Field's patent relates to a device for shifting the electric current from one telegraph line to another without disturbing the continuity of the current, thus enabling an operator to cut off his instrument from the lines without interfering with a passing message.

WINDMILL.—James and Wm. O. Swimmerton, Oakland. This invention is an improved windmill, consisting in mounting the windmill on a horizontal axis inside of a case or housing, which has openings in its sides suitably arranged to admit the wind to the wheel and in which the wind openings are regulated by slides, which can be adjusted to admit more or less wind as desired.

General News Items.

The mines closed at noon and Welsh patriotism and enthusiasm were unmistakably manifested in favor of the national institution. The officers of the day were: W. P. Morgans, president; F. Howells, adjudicator of compositions in poetry and prose; F. Howells and Rev. W. Parry, adjudicators of addresses and recitations; Professor Meredith, adjudicator of musical compositions and singing; J. R. Davies and E. John, scribes.

Employment Wanted.

Wanted, some kind of employment in the country. Can run a small engine or do many kinds of light work in farming. Reference furnished. Address B., this office.

SCALD head and numerous other diseases of the scalp, for the cure of which so many forms of ointments and plaster have been invented by medical men, can be simply and effectually remedied by washing the head with GLENN'S SULPHUR SOAP. Sold everywhere.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

HENRY NELSON, Merced Falls, is requested to address this office.

The Scientific Press Engraving Company.

As has been announced in our columns, this company is prepared to do fine wood engraving on favorable terms. Mr. E. Schultze, managing partner, served a thorough tuition in his branch of art in Germany and New York, and has since had over seven years' experience in designing, drawing and engraving in California. Customers can place their orders in Mr. Schultze's hands with the full assurance of receiving satisfaction as to quality of work and fairness of price.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1667.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly steemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO $5.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, $10.50; in leather, $12. Forwarded by mail for 500. extra, at the MINING AND SCIENTIFIC PRESS Office, by

DEWEY & CO.

Much Obliged, Etc.

PORTLAND, OGN., June 26th, 1876.

DEWEY & CO., Patent Solicitors, S. F.—*Gents:* I am much obliged to you for courtesy shown me, and am well pleased with the manner in which you have done my business, and assure you, will cheerfully recommend you to my acquaintances needing such services. Hope to have a case again before long, of my own. I have been an invantor all my life, but let others reap the benefit, or had work stolen from me. Please have the extra copies of my patent, etc., mailed to me direct, and oblige Yours truly, J. H. WOODBUM.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—California.
G. W. MCGREW—Santa Clara county.
J. M. MCARTHUR—Los Angeles, Santa Barbara, Ventura, San Bernardino and San Diego counties.
A. C. KNOX—El Dorado county.

CEAS. E. SAJOUS—Philadelphia.
A. O. CHAMPION—Tulare, Fresno and Kern counties.
RICHARD RULE—Nevada.

IMPROVED—Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS and the RURAL PRESS, now have the leaves of both these sixteen page sheets cut and stitched, which is an improvement that all readers of that otherwise inconvenient form of journal will appreciate very much. Every farmer would be a gainer were he to subscribe for the RURAL. It is decidedly a valuable paper, and the SCIENTIFIC PRESS is no less so to mining men.—Inyo Independent.

GOOD PRINTING INK.—We prefer Chas. Eneu Johnson's printing inks, having used them on this paper for the past four years. H. S. Crocker & Co., printers, stationers, blank book and paper dealers, are Johnson's S. F. agents.—DEWEY & CO., Publishers.

Eleventh Industrial Exhibition,

Under the Auspices of the

MECHANICS' INSTITUTE.

The Managers have the honor to announce that the forthcoming Exhibition will be opened to the public on

Tuesday, Aug. 8th,

At 11 A. M., with the usual ceremonies. By the desire and co-operation of the leading citizens of San Francisco, the Exhibition will be held on a much grander scale than heretofore.

THE EXHIBITION BUILDING, OCCUPYING AN AREA OF OVER 214,000 FEET

OF FLOOR ROOM, WILL BE COMPLETELY FILLED WITH THE VARIED PRODUCTS OF THE SKILL AND INDUSTRY OF THE PEOPLE AND OF THE SOIL. OVER 700,000 PERSONS WERE ADMITTED DURING THE LAST FAIR. THE MANAGERS INTEND TO ENGAGE THE SERVICES OF THE BEST INSTRUMENTAL TALENT OF THE COUNTRY, SO AS TO ENABLE THEM TO GIVE UNEQUALED

MUSICAL CONCERTS AFTERNOON AND EVENING.

In every Department applications for space far exceed expectations, and surpass those of former Fairs. Intending Exhibitors must not delay filing their applications, otherwise they will be excluded.

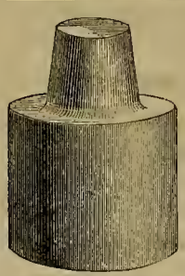
The Exhibition will Continue at least One Month.

THERE WILL BE NO CHARGE FOR EXHIBITING SPACE.

Application for space or for information should be addressed to the Secretary of the Board of Managers, Eleventh Exhibition, 27 Post street, San Francisco, or to J. H. Gilmore, Supt., at same address.

A. S. HALLIDIE, President.
J. H. CULVER, Secretary.

PATENTED

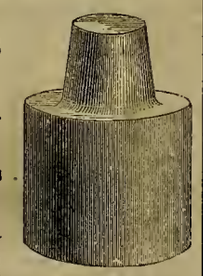


CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents to 12 Cents Per Pound.



Owing to our largely increased business, the present low price of Iron from which our Steel is manufactured and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED OAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at 12 cents per pound, delivered at San Francisco or Sacramento, instead of 16 cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gnt Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc.

Address all orders, with dimensions or drawings, to

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect **July 1st, 1874**, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"*The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated.*"

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Antilles Mining Company—Location of principal place of business, San Francisco, Cal.

Notice is hereby given, that at a meeting of the Directors, held the seventh day of July, 1876, an assessment of 20 cents per share was levied upon the capital stock of the corporation, payable immediately, in U. S. gold coin, to the Secretary, at his office, No. 207 Sansome street (third floor), San Francisco.

Any stock upon which this assessment shall remain unpaid on August 16th, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, September 8th, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

H. M. MORGAN, Secretary.
Office, 207 Sansome street, San Francisco, Cal.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of June, 1876, an assessment, No. 36, of five cents per share, was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, Room 13, No. 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of July, 1876, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the 5th day of August, 1876, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

O. H. BOGART, Secretary.
Office, Room 13, No. 328 Montgomery street, Safe Deposit Building, San Francisco, California.

The Manhattan Marble Company of California.

Location of principal place of business, San Francisco, Cal. Location of works, Oakland, Alameda county, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment, levied on the 23d day of May, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
C Beach	75	26	$ 75 00
C Beach	76	25	75 00
C Beach	77	25	75 00
C Beach	78	25	75 00
C Beach	79	19	57 00
D M Bokee, Trustee	269	7	21 00
D M Bokee, Trustee	260	3	9 00
E Tripp	302	5	15 00
E Tripp	303	5	15 00

And in accordance with law, and an order of the Board of Directors, made on the 23d day of May, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at the office of the company, 13 and 15 Fremont street, San Francisco, on Monday, the 17th day of July, 1876, at 12 o'clock M., to pay the delinquent assessment thereon, together with the cost of advertising and expenses of sale.

L. L. ALEXANDER, Secretary.
Office, Nos. 13 and 15 Fremont St., San Francisco, Cal

Mariposa Land and Mining Company

of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixth day of July, 1876, an assessment (No. 6) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 9 Nassau street, New York.

Any stock upon which this assessment shall remain unpaid on the seventh day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the second day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.
Office, Room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Union Consolidated Silver Mining Co.,

San Francisco, June 15th, 1876.

The annual meeting of the stockholders of the Union Consolidated Silver Mining Company, for the election of trustees for the ensuing year, and for the transaction of such other business as may properly come before it, will be held at their office, 311 California street, rooms 3 and 4, second floor, over Ætna Insurance Office (entrance 309 California street), on Monday, July 17th, 1876, at 2 o'clock P. M. Transfer books will be closed July 12th, at 3 o'clock P. M.

J. M. BUFFINGTON, Sec'y.

Umpire Tunnel and Mining Company.

Of Utah. Principal place of business, San Francisco, Cal. Location of works, Big Cottonwood District, Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 23d day of June, 1876, an assessment (No. 5) of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, 605 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 24th day of July, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 14th day of August, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

The ALLEN ENGINE GOVERNOR.

Fig. 1. For Variable Cut-Off Engine.

Uniform Speed in the Working of Steam Engines.

THE SIMPLEST AND MOST EFFICIENT GOVERNOR YET CONSTRUCTED.

ECONOMY and SAFETY.

Especially Valuable with Adjustable Cut-Offs. Capacity of Machinery Increased by Accurate Regulation of Speed.

Direct Saving of Fuel—Great Increase in Power of Engines.

The high rate of speed used acts advantageously in making the Allen Governor very sensitive; and all parts being lubricated, it works with the smallest amount of friction.

The speed of the Engine is maintained equally, without reference to the variations in amount of work being done.

The peculiar action of the Governor, which allows the use of a valve of large area, thereby admitting to the Engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced astonishing results by being attached to old engines, greatly increasing their power or effecting a direct saving of fuel, and in hundreds of instances doing both. In running an engine with the Allen Governor with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Allen's Patent Governor Valve is constructed with a double disc in a tubular frame, and is perfectly balanced, there being no spindle as in the ordinary throttle valve to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, insuring the greatest possible durability.

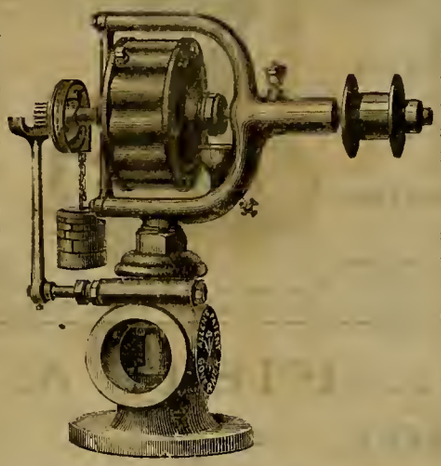

Fig. 2. Allen Governor and Valve.

We have Numerous testimonials from parties who have used this Governor, and watched its workings critically. In all cases the Governor has made the various engines to which it has been applied produce the most profitable results ever obtained.

Fig. 3. Section of Allen Governor.

PARTIES INTERESTED IN STEAM MACHINERY SHOULD EXAMINE THE ALLEN GOVERNOR, WHICH IS NOW INTRODUCED ON THIS COAST FOR THE FIRST TIME. FULL INFORMATION CONCERNING IT CAN BE OBTAINED FROM ILLUSTRATED DESCRIPTIVE CIRCULARS WHICH WILL BE SENT ON APPLICATION. Address,

SODIUM AMALGAM.

I am prepared to furnish Sodium Amalgam for $1.50 per pound. Although the price is low, my reputation is a guarantee of its purity. Sodium being now much cheaper than formerly, the miner and millman should have the advantage of it. The temptation to adulterate the article being so great, consumers are advised to call for my manufacture when ordering from wholesale dealers, with an assurance on my part that the quality will be the best. Zinc is sometimes substituted for sodium, to the great disadvantage of the consumer. The following are the tests for pure Sodium Amalgam: Shaken up with water it must be wholly decomposed, the mercury remaining perfectly fluid and the water becoming strongly alkaline.

VOLUME XXXIII Number 4.

Fire Proof Buildings.

Jules Borie's Patent Hollow Bricks.

The innumerable cases of destruction by fire which desolate this country, and culminated a few years ago in the calamities of Chicago and Boston, seem to have made a lasting impression on the public of the East, and ought not to be overlooked by the people of the Pacific coast. We are all aware that of the dangers which hang over us inhabitants of cities, none is more serious than this. We can keep away epidemics by good drainage, police regulations, cleanliness and other means. The Eastern man has it in his power to order back to the clouds, so to speak, the thunder bolt which threatens his dwelling. But if our warehouses, stores and dwellings are made of wood, there is no safety for us whatever; our lives and properties are day and night the ready prey of a foe which knows no mercy. We pour immense sums of money in the hands of insurance companies without perceiving that when requested to help us they cannot cover all the losses which we have sustained. We do not realize to its full extent this well established fact that the extra cost of an approximately fire-proof building will be paid, within a few years, by the mere saving of the rate of insurance; moreover, that a tenant will always be glad to submit to a higher rent for a place where he feels that his family, merchandise, furniture, papers and other valuables shall be safe.

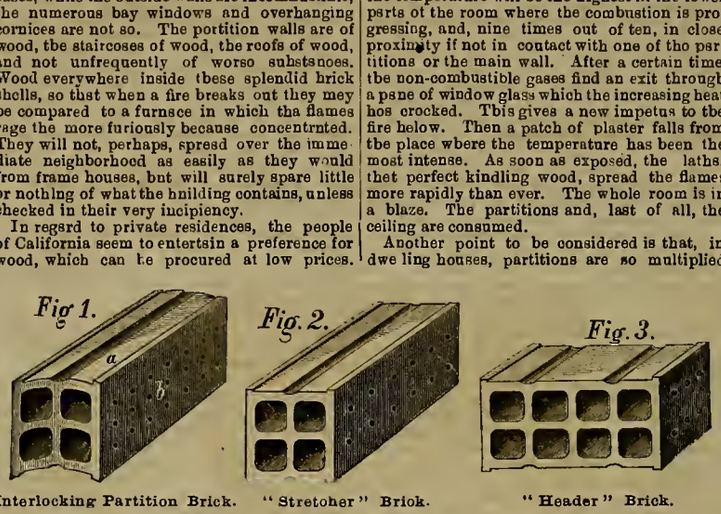
The movement towards fire-proof constructions began in Europe 25 years ago, and was promoted by the introduction to market of iron beams combined with Borie's hollow or, as they were called at that time, tubular bricks, which we purpose to describe in this article. Their consumption has been ever since on the increase in England, France, Germany, Belgium and other countries. In Paris, for instance, few substantial houses and no public buildings are erected without them. Notwithstanding the abundance and cheapness of stone, the partitions are not untrequently the main lateral walls are made of hollow bricks, the use of wood being limited to the floors, windows, doors and the like. As a general thing the cost of these improved structures does not figure 15 per cent. over that of houses in which formerly wood was lavished, and the rates of insurance are almost nominal, usually one-tenth of one per cent. of the valuation.

This wise policy has been highly remunerated, for to it the city of Paris is indebted for its preservation. Just after the German war the Communists, who, for three months had the control of the town, tried to burn it. Hundreds of them were seen every day forcing their way into private residences, business places and public buildings, pouring petroleum on the floors and furniture, setting matches to it, and thence proceeding again with their work of vandalism wherever they had a chance to accomplish it. They were not successful, and the destruction was confined to a few houses and palaces which were particularly combustible. When on a visit to that capital, the American citizen seldom fails to notice the absence of gorgeous fire engines, mounted hook and ladder companies, fire-alarm boxes, etc. He can only see a few hand pumps and ladders carried along the streets by the firemen on foot.

Of late years our large Eastern cities have determined to fight with energy and perseverance the common enemy. Many constructions made fire-proof, or nearly so, may be seen already in New York, Boston, Philadelphia, Chicago, St. Louis, etc. In Chicago rows of cheap houses of this kind have been lately built through the liberality of the Merchants', Farmers' and Mechanics' savings bank. The boards of underwriters are making, all over the land, incessant efforts in the same direction. The impulsion is given. All men of practical and philanthropic sense understand that a question in which every one has an interest is simply a national one, and there is no doubt that in time this great problem of public safety will be solved on a large scale east of the Rocky mountains.

In this State San Francisco and a few other cities are subject to fire limits. These include their main business streets, where numbers of brick structures stand which any town in the United States and Europe would be proud of. At first sight this seems to be a progress in the right line. Unfortunately there is in it more show than reality. In the great majority of cases, while the outside walls are incombustible, the numerous bay windows and overhanging cornices are not so. The partition walls are of wood, the staircases of wood, the roofs of wood, and not unfrequently of worse substances. Wood everywhere inside these splendid brick shells, so that when a fire breaks out they may be compared to a furnace in which the flames rage the more furiously because concentrated. They will not, perhaps, spread over the immediate neighborhood as easily as they would from frame houses, but will surely spare little or nothing of what the building contains, unless checked in their very incipiency.

In regard to private residences, the people of California seem to entertain a preference for wood, which can be procured at low prices.



Interlocking Partition Brick. "Stretcher" Brick. "Header" Brick.

Moreover, they contend that brick walls get damp during the long rainy season and are not as secure as could be wished against heavy earthquakes. For the cheapest class of houses, wood is undoubtedly, and will be for years to come, the main resource. For residences of a higher description, it is claimed hollow bricks will overcome easily the two latter objections.

It is not without some interest to briefly mention how a fire usually originates, and which are the parts of a building best situated to propagate it. Leaving aside the danger arising from the vicinity of an outhouse, a stable for instance, where straw, hay or chips may be ignited, reference is made especially to business places and dwelling houses, which are the most numerous in any city, and where consequently conflagrations are the most frequent. Let us take as an instance a room surrounded by wooden partitions and furred brick walls. In case of arson, the criminal will generally accumulate some inflammable compound in under a closet, a bed, or in the corner of the room, impregnate it with oil and run away. In the case of mere accident: a defective chimney flue; a match in the hands of a child; a lamp which will explode or be left near some piece of light furniture, cotton garments, a curtain or the like; reading while in bed; a heavy spark flying on a carpet after the inmates have retired; these are about the most common causes. The fire is started. Some people might think that hot air having a tendency to ascend, the part of the room to be likely destroyed first will be the ceiling. This is a mistake. In a chimney flue, for instance, the heat decreases in a greater ratio than the distances of any given point to the fire place, and if a damper is applied to this flue, some idea may be formed of what will occur in the burning room. The non-combustible gases generated by the first blaze will gather under the ceiling, which operates in this case as a kind of damper. They will, for a while, keep down the tongues of the flames or, perhaps, owing to some admixture of air, will allow them to faintly leap and blacken the ceiling without doing it any serious injury. On the contrary, the temperature will be the highest in the lower parts of the room where the combustion is progressing, and, nine times out of ten, in close proximity if not in contact with one of the partitions or the main wall. After a certain time the non-combustible gases find an exit through a pane of window glass which the increasing heat has cracked. This gives a new impetus to the fire below. Then a patch of plaster falls from the place where the temperature has been the most intense. As soon as exposed, the laths, that perfect kindling wood, spread the flames more rapidly than ever. The whole room is in a blaze. The partitions and, last of all, the ceiling are consumed.

Another point to be considered is that, in dwelling houses, partitions are so multiplied that their exposed surfaces are far more extensive than those of the main walls, which consequently, even when made of wood, cannot be as dangerous.

Insurance companies are well aware of this fact: that furniture, wooden floors, doors and windows are not liable to start destructive conflagrations. They do not object to wooden beams. When these are protected, just under the floors, by a layer of isolating material, the coat which forms the ceiling being supported by a non-combustible substance, instead of laths, they maintain that such buildings are as nearly fire-proof as can be desired for habitation, and reduce their rates accordingly. But they never fail to charge heavily when wooden partitions are used, even in connection with brick or stone walls.

CONSTRUCTION OF PARTITION AND WALLS.

Thus it will be seen that wooden partitions ought to be done away with wherever there is any regard for safety in buildings. They are at a disadvantage in other respects. The plaster which covers their laths is liable to crack, and gets defaced by the least touch of a piece of furniture, driving of nails, etc. They also conduct the sound so well that a conversation at low voice can be held through them from one apartment to another. But they are cheap and light on the supporting beams, two important items which explain why solid brick partitions are not patronized in this country though their use has been general in Europe from time immemorial, until superseded by hollow bricks, the most prominent features of which we are now going to describe.

As before stated, hollow bricks made their appearance a quarter of a century ago. They were the invention of Borie Brothers, of Paris, and in a great measure helped improving the modes of building of that metropolis. However, they were far from being perfect. Their faces were too smooth, which caused the plaster to peel off, unless of first quality and worked with care. Their shape was too complicated, and required the best raw material, by which the selling price was kept comparatively high. Again, no provision was made for them to interlock one another and thereby form a well bound construction, which is the main point in such thin walls as partitions are. These defects have been obviated by Jules Borie, one of the original inventors, and the improved hollow bricks, for which a United States patent has been issued to him lately through the Mining and Scientific Patent Agency, will be found to answer all the requirements desired in this important matter, as will be seen by the accompanying engravings.

Fig. 1 is a brick especially intended for partition purposes in ordinary dwellings. It contains four longitudinal cavities. Its transverse section is four by four inches, and length eight and one-half inches, thus being nearly double the size of a common brick. For stores, warehouses and public buildings it is made larger. Of its abutting ends one is concave the other convex, so that they interlock with the next bricks of the same course. Both its laying faces, one of which is seen in *a*, are grooved; consequently the mortar operates as a key between all the courses of bricks. A small quantity of mortar enters also from the vertical joints into the cavities and forms a new key. The studdings of the doors are each provided with a vertical groove which leaves a small space between them and the bricks. This space the mortar penetrates, making a third key. As for the lateral surfaces of the brick, one of which is represented in *b*, they are perforated with a certain number of small holes which allow the plaster to go through the shell and clinch on its inner surface, thus giving the coating a perfect adherence to the brick. By these means the whole partition forms a compact strong body, which will defy a commotion as successfully as any well built outside wall.

Fig. 2 is also a partition brick, which only differs from the former by its ends being cut square instead of curved.

Fig. 3 shows a brick containing eight transversal cavities, and is what builders call a "header," while the brick Fig. 2 is a "stretcher." By using both of them a wall of any thickness is built. When erecting the angles of walls of this kind, the bricklayer uses the few headers wanted for the purpose, with their cavities set vertically, instead of horizontally. He fills these cavities with sand within one-half an inch or so of the top, and then applies the mortar as usual. By this method none of the cavities are exposed, and the angles hold firmer than when made of solid bricks.

Fig. 4 represents an eight and a half inch wall, c, c, and a four inch partition, *d*, both in progress at one time. Each course of the partition crosses joints with the corresponding course of the wall, thus giving the structure the utmost stability. On the exposed faces may be seen the small perforations intended to hold the plaster, a few patches of which are shown in the engraving.

The above bricks, which are the best for common use, as well as those of any size and shape intended for ornamentation and other architectural purposes, are made of burnt clay, cement, plaster, or similar compounds. However, clay is the best and cheapest material. It is thoroughly worked and molded by a small machine, in which a high pressure is produced, which turns out these well shaped forms by thousands in a day.

Their weight is less by 55 to 60 per cent. than solid bricks of the same size would be. Consequently no large foundations are necessary for supporting the main walls, nor are heavy beams for bearing the partitions made of them, to say nothing of the safety which follows when lateral pressure has to be reduced, as, for instance, in vaults, arches, etc.

Their cavities keep the inside of the walls permanently ventilated and dry, which does away with the dangerous practice of furring and lathing.

Being bad conductors of heat, cold and noise, they make houses warmer in winter, cooler in summer; they are the healthiest building material yet found. On account of their difficulty of being penetrated by sound, places

(Continued on Page 68.)

CORRESPONDENCE.

Overland Chat.

[Written for the PRESS by MARY MOUNTAIN.]

When we first trudged through the streets of Chicago, we began to say, "Why it seems like San Francisco, don't it?" Only the air is so smoky and dirty and murky, it don't seem good to breathe, and how it shuts out the distance. Ten blocks away everything is dingy and obscure.

And how funny the street cars look, open at the sides, and some are entered at the sides, with seats arranged across instead of lengthwise. Many of the wagons, trucks and carriages look quite different from ours, and we notice that nearly everybody carries an umbrella, and needs it very often, too, in the course of the day, for the pelting showers come down almost without warning.

Passing through the burnt district, we found several vacant lots with ruins, almost as the fire had left them, and at the railroad station, so little has been rebuilt, that we found a waiting and ticket room much smaller and rougher than an ordinary farm kitchen. From Chicago to Titusville, Pa., we passed through the lake shore country, and had expected to find it "all alicked up" and reposing in a sort of elegant leisure. So we were disappointed, and especially with the first farming country eastward of Chicago, where stumps, swamps and the "ragged edge of despair" were most noticeable.

Through Ohio the farms look better and as if the owners take agricultural papers and save up egg money for paint and whitewash. We saw very little stock and none better than the average in California.

Titusville

Was our next stopping place, and if the man in the moon should drop down there with a human nose, he would need to ask no question about its leading industry, for the air is full of it, and the new comer will soon "take it in at the pores" and smell as good as anybody.

The relatives we came here to visit are old settlers, and years ago had told us of the oil that floated on the creek, and how it was sometimes soaked up in a blanket, wrung out and used as an excellent remedy for rheumatism, also as an occasional make-shift for light and for lubricating. There is evidence that some former race knew of this oil and collected it in pits dug along the river bank, and in many of these pits large trees have grown, perhaps generations of trees since.

The Unknown Race "Struck Ile."

Mr. Drake was the lucky and famous man who bored the first well and pumped the first oil in this region, and his old derrick, pump, etc., have been sent forward for the Centennial exhibition.

Much more remarkable wells were soon struck, some bursting out with terrific explosions that sent oil and gas high in the air, and catching fire from the engines immense damage was done before people learned how to control these dangerous elements.

Titusville is in three parts, the beautiful, clean and green, where oil princes live in big, handsome houses, and plenty of other people in commonlcottages; the business section, where merchandise and oil stocks are offered "cheap for cash;" and the oil soaked region by the river where you will find eight refineries; paraffine works, color works, acid works, machine shops and the most enormous tanks, holding 30,000 barrels of oil each.

Measuring one of these tanks, it was found to be 100 feet in diameter and 20 feet high, made of boiler-plate iron riveted together. And here are the iron pipes that bring oil in from the different districts; 12 or 15 of them cross one bridge, some of them 15 miles long, and the oil is forced through them by huge steam engines located at the wells.

The big kettles holding 3,500 barrels each are another curiosity, for the intense fires are kept up by the gas escaping from the oil, and the town is also lighted with gas from the wells in the hills.

It is always considered a good joke to talk of

Setting the River on Fire,

But the good folks of Titusville have reason to pray that no one will try that joke on their river, for they know already how well it will burn. The town has 13,000 inhabitants, and the daily product of oil is about 24,000 barrels.

At Pleasantville, six miles up in the hills, our friends took us to see the boring of a new well; also to see the best yielding well in the place, and we crept up on the greasy derricks to look at the steady black stream that would fill a three-fourth inch pipe, and is worth to its owner about $1,000 per week. The owner is a rough, crude looking man, and with the help of his Irish wife does all the work and keeps down the expenses, so they will soon have a fortune for those ragged little children we saw in the shanty close by the well.

Throughout the oil district the average yield is slowly diminishing, and hundreds of wells are abandoned. To bore a new one takes 20 days and costs some $2,000, and men are constantly hunting for new districts as the old give out. When a well goes dry the derrick is left standing, and in some districts there were more than I could count. A barrel factory turns out 1,000 barrels per day, made from oak wood cut in this vicinity.

The crude oil is now worth $2.18 per barrel—was once as low as 25 cents, and at that time the grocers of this vicinity were in the habit of giving to their regular customers all the oil they could use—and the best refined oil has been sold at five cents per gallon.

Our trip to Philadelphia through the

Lehigh Coal Region

Was full of interest, not only on account of the wonderful scenery, but the immense amount of business along the many iron roads was a rich surprise for us, and took away the very last rag and remnant of our California brag. We fairly turned pale as we whispered so that no one might hear—"Do you think California ever will show so many big towns that make no fuss over being big and doing such a perfectly awful rush of business?" Market street in San Francisco seems busy, but does not begin to give that tremendous impression of vast business operations which struck us so forcibly during one day's ride in the old Keystone State.

The Defiance Strike.

Being informed that another bonanza had been struck in the Defiance mine, the editor of the Coso *Mining News* has visited the mine and says:

From the mouth of the main tunnel we passed through a drift in the front vein, called ledge No. 1, southerly and on a level with the main tunnel a distance of 100 feet, all in fine galena ore. At the extremity of this drift or level, is sunk a shaft 40 feet deep in ore and connecting with another drift or level on the front vein running south along the vein 155 feet, in the same character of ore as on the upper level, making a distance of 245 feet south from the main tunnel. At the extreme end of this level is sunk a shaft 50 feet, showing ore all the way down and of a superior quality at the bottom. The depth from the bottom of this shaft to the surface croppings of the front vein is 300 feet. Nowhere along the line of these drifts have the foot or hanging walls been struck. Returning to the month of the main tunnel, and about 30 feet south of it, is sunk an incline 60 feet deep, from the bottom of which runs a drift northerly along the vein 60 feet in very fine ore. Also from the bottom of this incline shaft a crosscut is run east toward the foot-wall 25 feet, in carbonate ore, with no indications of the foot wall. The body of ore now visible in the crosscut and extending across the front ledge is not less than 40 feet. How much further it extends remains to be solved by further development. We now go through the main tunnel and at 165 feet from its mouth we went through a chute rising to the surface through the north workings of vein No. 2, and everywhere were vast chambers of carbonate and galena ores. From the floor of the main tunnel to the surface is 150 feet. The tunnel now being run from the mouth of main tunnel to tap vein No. 2, is now in 125 feet and ore has already made its appearance. An immense body of ore lies immediately north of this tunnel. Proceeding further in, in the main tunnel 175 feet from the mouth, we enter a drift running south 84 feet in vein No. 2, where at that point it is crosscutted a distance of 25 feet, showing a magnificent body of ore, and the crosscut progressing with no indications yet of either wall. Again we return to main tunnel and move forward to the grand "bonanza," where it breaks through the floor of the tunnel at 300 feet from the mouth, and at a distance of 250 feet from the surface. Here there are several stratas or feeders apparently dipping toward vein No. 3, which appear to be about five feet in width on the floor of the tunnel. An open cut is now run across the floor of the tunnel and is sunk below the floor 25 feet. This cut is ten feet wide at that depth, all in splendid chloride ore, and the vein widening as it goes down. Two drifts are now started, running north and south on this vein, with the same result as at the centre of the tunnel. To say that this is the finest smelting ore we have yet seen in this mineral section would give no conception of its true value. It is the finest body of ore to be seen outside of the famous Raymond & Ely mine when it was in its glory. As to its permanency we have no doubt. The vein dips into the hill; the ore is soft, compact and solid, with no foreign substance intermixing, as in the front vein. The ore resembles the rich yellow ore of the Raymond & Ely. From three assays made yesterday, and taken at random—for there is no choice in the ore—they went $234.25, $443.14 and $465.44. We are overjoyed at the good fortune of the lucky owners. They spent their money without squealing, and now may congratulate themselves on their success. At 75 feet from vein No. 3 we find another body of ore of a somewhat similar character. This last body of ore is about 10 feet in width with similar feeders running toward it as in vein No. 3, as this vein, as yet, has not been opened to any extent, we may indulge the hope that it will prove another great bonanza in the Defiance.

A GOLD VARNISH.—Researches made by M. Kayser, of Nuremburg, have shown that a gold vernish, distinguished both by its hardness and beautiful color, may be obtained by the use of picric and boracic acid. A very pure solution of gum lac should be mixed with picric acid and about half per cent. of crystallized boracic acid, the two acids having been previously dissolved in alcohol. In this way a gold varnish may be prepared, possessing all the advantages of those that are met with in commerce.

Coal Resources of Contra Costa County.

Among the Contra Costa county Centennial papers, is one written by J. T. Cruikshank on the coal and other resources of the county east of the Mt. Diablo meridian. This has been published in the Contra Costa *Gazette* and we extract from it what pertains to the coal mining interests, giving as it does a history of that industry in the county:

In 1859, at Horse Haven, six miles south of Antioch, William C. Israel, in cleaning out a spring on his land, discovered a vein of coal. In connection with his father and brother George, he opened the vein for a short distance; but, not having capital to work it, they disposed of their interest to James T. Watkins and — Noyes, who, either from want of knowledge or capital, failed in opening the vein so as to make the working of it successful. They abandoned the mine in 1861. It has not since been opened.

On the 22nd of December, 1859, at a distance of three and one-half miles west of Horse Haven, Francis Somers and James T. Cruikshank discovered the vein of coal which has since become so well known as the Black Diamond vein. Somers, Cruikshank, and their associates, H. S. Hawxhurst and Samuel Adems, located the lands which were afterwards known as the Manhattan and Eureka coal mines.

George Hawxhurst, George H. P. and Wm. Henderson, in company with Francis Somers, opened the cropping of the same vein, on what was afterwards known as the Black Diamond and Cumberland mines. But, believing that the expense of making roads was beyond their means, they made no attempt to secure title. The Black Diamond mine was shortly after located by Noah Norton, and the Cumberland mine went into the hands of Frank Such and others. These lands, with others adjoining, have since became noted as the Black Diamond coal mines.

The Pittsburg mine, east of the Eureka and towards Horse Haven, was located by George H. P. Henderson, who entered into a contract with Ezra Clark to open the mine, in the opening of which the vein of coal known as the Clark vein was discovered.

The Central coal mine, east of the Pittsburg, was located by John E. Wright. The year following Wm. B. Stewart became connected with it and still remains so.

The Union mine, north of the Manhattan, was located by George Hawxhuret.

The Independent mine, north of the Eureka, was purchased from Major Richard Charnoch by Greenhood and Neubaner.

The Manhattan, Union, Eureka and Independent, comprise the mines forming the basin in which the town of Somersville is situated, and from which there is a railroad for the transportation of coal to Pittsburg Landing, on the San Joaquin.

The Cumberland, Black Diamond, Mt. Hope and other lands, comprise the basin of the town of Nortonville, and from which also a railroad exists for the transportation of coal to Black Diamond Landing, at the head of Suison bay. From the mines enumerated there is about one hundred and twenty thousand tons of coal per annum shipped.

The Central coal mine, although taking out large quantities of coal has no railroad. The coal is hauled by teams to Antioch, on the San Joaquin river. The property is owned by a corporation.

The Empire company opened this year. Have a magnificent vein of coal, and have already contracted for a hundred tons of coal per day. They will soon have a railroad to the mine. The Empire is six miles south of Antioch, and within three-fourths of a mile of the first opening made on the coal veins of the county by the Israels. The mine is owned by George Hawxhurst and John C. Rouse. Openings on the veins from that mine to the Brentwood coal company's works on Marsh's grant have been made, which show that our county has an abundance of fuel to last until the next Centennial year, even if the demand should increase a hundred fold greater than it is at present.

The coal mining interest is becoming rapidly one of the most important ones of the county. It has already built up four towns, viz: Somersville, Nortonville, Black Diamond and Pittsburg Landings, and added greatly towards the progress of Antioch, which place was settled upon in 1849 and 1850 by Parson W. W. Smith, George W. Kimball and J. C. McMaster. The town had no trading post until 1861, when Martin Homburg, now the owner of a fine large brick store, well stocked with merchandise, erected a small building about 20 feet square; since which time its growth has not been rapid but permanent. In the future its growth will be more rapid than in the past. There is south of the town three thousand eight hundred and forty acres of coal land—that is coal lands that can with profit be worked—containing 5,184 tons of coal to the acre, in all 10,906,460 tons, all of which must have its outlet at Antioch. Iron, gypsum, cinnabar, potter's clay, and hydraulic cement rock are found south of Antioch, the two latter in large quantities. Also petroleum, but of such great specific gravity that it will not penetrate through the shales and sandstone. If ever worked it will be by distillation. There is an abundance of it, but it can probably be obtained at less cost from the lower counties of the State than it can be produced for here.

The Fan Method of Ventilating Mines.

We gave in our last issue some details of the operation of the Guiboldt fans in the coal mines in England. One of these fans has been put up in the Gould & Curry mine, on the Comstock, and is thus spoken of by the Gold Hill *News:*

We had the pleasure yesterday morning of viewing for the first time, in full operation, the new Guiboldt suction fan, recently erected under the superintendence of Colonel James G. Fair, at the mouth of the old Gould & Curry tunnel. This fan is a piece of ventilating mechanism entirely different in its operations and results to anything ever before erected on the line of the Comstock. Superintendent Fair, who always has his eyes open for anything in the shape of improvement in mining machinery, found one of the fans in operation at one of the coal mines in Pennsylvania, while on a visit last summer to the East, and struck with its good success as a ventilator, brought with him a plan for the machine, and at the same time ordered from the manufacturers at Wilkesbarre, Pennsylvania, the Guiboldt patent arms necessary for the construction of the fan. Upon his return to Virginia City, an immediate order was given to the Pacific Iron works in San Francisco for the manufacture of boilers, engines and other necessary running machinery. This machinery consists of two upright engines each having a 14-inch cylinder and a 30 inch stroke. The steam for these engines is supplied by two 54-inch tubular boilers, each 16 feet in length. Either engine has sufficient power to drive the fan with ease, in case the other may need repair. This machinery, on its arrival, was erected at the mouth of the tunnel. The mouth and sides of the tunnel were then boxed up air tight, and a chamber of 22 feet in hight and 15 feet in width, constructed in such a manner that the entire volume of air drawn through the full size of the tunnel could have no other exit than through an escape purposely constructed in the top of the chamber. In the center of this air tight chamber is built the fan, it being again enclosed in a casing nine feet in width, in the top of which is the escape. On the other side is left an open space through which the air is drawn when the fan is in motion. The diameter of the fan is 20 feet, and the paddles eight feet in length by five feet in width. Under ordinary circumstances it is run at a speed of 70 or 80 revolutions per minute, which speed can be greatly increased whenever it is desirable to do so. At the time of our visit, the air drawn from the mouth of the tunnel had about the speed of a strong gale, or was traveling at the rate of 60 miles per hour. The simplicity and beauty of the principle is understood at a glance. When this immense volume of hot air is being drawn from the lower levels of a mine through one shaft, it naturally creates a vacuum, which must and will be supplied by fresh air from the surface so long as there is another shaft or opening through which it can descend. The effects of the new ventilator are already being felt to a powerful extent in both Gould & Curry and the Best & Belcher mines, and even extend into the Consolidated Virginia. In the Best & Belcher and Gould & Curry, where the thermometer was at 120 to 130 degrees before its starting up, the temperature is now only from 90 to 95 degrees, and is still steadily decreasing. Mr. Fair deserves and should receive great credit for the introduction and operation of not only this, but many other practical improvements in the machinery for working our deep mines. There is nothing so valuable in the working of a mine as good ventilation. It not only vastly increases the health and comfort of the workmen, but enables them to do double the amount of labor in a given length of time, and will thereby alone return to the stockholders an hundred fold the cost of such machinery.

The Central City Tunnel.

This tunnel, says the Colorado *Register*, is a new enterprise and one of no little importance when considered in the light of the results likely to be achieved from the accomplishment. The tunnel is to be of the uniform size of five and one-half feet wide by six and one-half feet high, and is to be driven through Quartz hill to the vicinity of Leavenworth gulch, a distance of 3,000 feet. Its starting point is in Nevada gulch, a short distance above the mouth of the Quartz hill tunnel, and its direction will be 24 degrees, 51 minutes west of south. Over 30 lodes, more or less developed, are in its course, including the famous Borroughs, Roderick Dhu, Illinois and others, where a depth of 500 feet and over will be attained. As the tunnel will thoroughly explore that part of this wonderful depository of wealth, many blind lodes and extensive ore deposits are likely to be met with. These will furnish a large quantity of ore, while for drainage purposes and as an ore outlet for the mines, it will prove of great benefit to both owners and miners generally. This tunnel site was located in November, 1874, by D. G. Wilson and B. O. Russell, two well known miners of the olden time, who have since organized upon it the Central City tunnel company. Recently Mr. Wilson returned from New York and immediately began the work of driving the tunnel, which is now in 22 feet. A blacksmith shop will be put on the large level plat of ground fronting the gulch. The Adeline and Lewis cluster of lodes will be intersected, and the Fortune lode, that has yielded so well, and is owned by the company, will be cut at a distance of 720 feet and 320 feet below the surface.

MECHANICAL PROGRESS.

New System of Grinding in Germany.

Soma commotion and lively discussion has lately been caused iu Germany and Austria by the announcement that a Mr. Vincent Till, who owns a mill and bakery at Bruck on the Main, had discovered a new process uf grinding grain into flour, which enabled him to make 100 lbs of fine white bread unt of 80 lbs of wheat. Tha *Muehle*, which is the official organ of the society of German millers, said, in one of its October numbers:

Cylinders are undoubtedly destined to play an important part in milling. Yet, however important they may ba, they will alwnys he secondary to a machine which will completely remove the hull of the grain before grinding. Such a machine I have finally, after experimenting for many years, invented. With this mill I can remove every visible trace of the hull while tha grain is dry; and I can, moreover, remova one, two or even three coats from tha kernel, without in the least injuring or losing eny purt of the remainder. When this is accomplished, all the nourishing parts of the grain may be mede into flour; and 126 lbs. of bread may be mada out of 100 lbs of grain. By means of this shelling-machine (*Schaelmaschine*), with a good breaking machine (*Getreidebrecher*), and a smooth cylinder ron, 70 lbs of the finest flour may be made out of 90 lbs of wheat; while with hurrstones, only 20 or 30 lbs. can be produced. Burrstones are an unstacle in milling, and ahould ba done away with.

The inventor, continues the *Muehle*, has sent na a small sample of shelled rye, which has an excellent appearance, and is superior to anything we have ever seen turned out by a dry smutter.

We give the details of Mr. Till's process, as they are set forth by the inventor himself: A condensed sketch of the process is as follows:

1. The grain is oulled by means of a separator.
2. It is subjected to the action of the smut-machine, or wheat-scourer. (The German expression means, literally, shelling-machine).
3. Each kernel is crucked or broken into ten or twelve pieces, by smooth-cylinders.
4. These groats are ground hy cylinders.
5. The product is then subjected to the separating reel.
6. It is then assorted by the middlings purifier.
7. The middlings is then again ground by cylinders.
8. The coarse bran is again grouud by cylinders, as before, and is then
9. Subjected to the holting-chest.—*Miller and Millwright.*

New Electric Motor.

An ingeniously arranged electric-motor has been exhibited in London during the past week by Mr. Chutaux, uf Paris. When recently shown at the Palais de l'Industrie it was awarded both silver and bronze medals for its simplicity and practical superiority over other instruments of its class. The primary force is supplied by a battery of eight or more cells, being a modification devised hy Mr. Chatsux of that of Bunsen. The elements used are graphite and unamalgamated zinc, the exciting fluids being sulphuric acid and bichromate of potash in the inner (or graphite) cell, and a solution of acid sulphate or bisulphate of potash in the outer (or zinc) cell. No smell is emitted from the battery, it is stopped and started without trouble, is very constant, and will last for a long time without renewal. No material action is exerted on the zinc while the battery is at rest, hence the reason for dispensing with the process of amelgamation with mercury. Two or more horse shoe electro-magnets, with their poles upwards, are worked by the current, a wheel rotating on a horizontal axis immediately above and almost touching them. This wheel is practically formed uf two parallel wheels, joined by a series of soft iron bars. As soon as the current is set up the wheel begins to revolve, owing to the attraction between the electro-magnet and the iron, the motion being kept up and rapidly increased by means of a simple antomatic "current reverser." The principal feature to which the inventor draws attention is the construction of the transverse soft iron bars, each of which is composed of seven thin plates, much being thus gained in intensity of magnstization, and consequently in mechanical power. By a series of ingenious devices the machine is applied to working of pumps, sewing machines, lathes, etc., as a substitute for manual or foot labor. It is not, of course, in any way intended to supercede steam, its object being the simple and easy performance of labor of a light description.—*London Mining Journal.*

An Ingenious Contrivance.—An apparatus has been attached to the rear of the pey-car used on the middle division of the Pennsylvania railroad, which is expected to be of important service to the officers of the road when on tours of inspection. A roll of white paper 700 feet in length encircles a cylinder, from which it is paid out at the rate of three feet to the mile, run by the car, its forward movement being regulated by the revolutions uf the nearest axle under the car. A lead pencil, placed about the center of the paper, indicates by its mark the condition of the track. The more uneven tha track the longer will be the mark which the pencil will meke. Another way of showing the inspecting parties thst the track is uneven, is hy a horizontel piece of iron or steel, which oscillates like the pendnlum of a clock, as the train moves. When a very defective point is reached, the pendulum comes in eoutact with a metal on each sida, circular in shape, and creates a sound lika that of a bell. This new invention is expected to work much more satisfactorily than the telegraphic apparatus formerly in operation.—*Philadelphia Inquirer.*

English Quarry Working.

At the Ridge quarries, Corsham, Raudall & Saunders are getting out the Bath stone, which is extensively employed for building purposes. The bed of stone worked at these quarries is a member of the Bath or Great Oolite, is 16 feet thick, and lies at from 80 to 100 feet below the surface. The stone is removed by the pillar and stall system, the overburden and surface being left undisturbed; communication with the surface is effected hy an shaft inclined at 45 deg., the traveling road for the men being provided with well out steps. The face of a heading is first attacked by holing in the stone immediately under the roof, and the men use their tools with marvelous rapidity and skill in effecting this operation. The stone having tu be removed in large blocks, the holings, or as they are locally termed "jads," have to be cut horizontally from seven to eight feet in from the face, and to secure as little waste of stone as possible, they must not be deeper vertically than 10 inches. The tools employed for this purpose are the jadding pick and the jadding iron. The head of tha pick measures 16 inches from tip to tip, and weighs from five to seven pounds. It is set obliquely upon the helve, which varies in length from three to five feet, the shorter length being employed at the commencement, the latter towards the completion of the hole. The jadding iron is a long bar, with a steel chisel edge, employed to deepen those jads which have to be cut beyond the reach of the picks, and is made to act by being forcibly projected against the surface; it is also very serviceable as a lever. The ability to swing a pick having a helve five feet long, close under the roof into a jad five feet deep horizontally, and varying in vertical depth from 10 inches at the face to four inches at the cut, with the velocity necessary to chip the rock, and with the requisite accuracy of aim, is only obtained by long practice. The bold delivery of the blows in rapid succession, and the peculiar rocking motion of the body in the recovery after the stroke attract the notice of visitors, and call forth their admiration at the skill of the workmen. The side or back cuts, which must be made before the block of stone can be removed from its bed, are effected by the use of saws. Each stall has a powerful crane fixed in it, and when the block of stone is ready for removal a lewis bolt is fixed in its face, and the crane put into action. The surface of the block is then dressed with an axe by hand labor. It is now ready to be sent to the surface. This is easily accomplished, tramways being laid throughout the workings and along the inclined shaft. Horses are employed to yield the motive power underground, and one of Brown and May's 10-horse power portable engines is stationed at the surface, and turns the drum upon which the chain employed for hauling is coiled. The tramways is continued with a gentle gradient to the Great Western railway, the force of gravity being the motive power utilized in the descent of the loaded trucks, horse power bringing back the empties and stores.—*English Paper.*

Counterfeit Coins.—From the report of the deputy master of the mint, just published, we learn, says an English exchange, that prosecutions for manufacturing spurious coin are gradually decreasing, they having fallen from 387 in 1860 to 180 last year—the number of prisoners involved being for these periods respectively 887 and 327. The coins most frequently counterfeited are half-sovereigns, florins and shillings, and the skill and science applied to this nefarious manufacture have evidently increased. The most difficult part of the genuine coin to imitate is the milling around the edges; but some of the counterfeits are so well executed that they can only be detected hy careful examination. Ringing is not a certain test, for a slight crack renders it inapplicable, even frequent ringing has the same effect.

Metallic Pyrometer.—A bar of copper is, according to the invention of Mr. A. F. Huet, of Paris, enclosed within a porcelain tube firmly fixed within the surface. The end of the copper bar is rigidly attached to the end of the porcelain tube. The other end of the copper bar is pivoted to one end of a lever, pivoted at the other end to a rod ending in a piston moving in a cylinder filled with liquid. A thermometric tube leads into the bottom of this cylinder, and upon a scale marked upon this tube the rise and fall of the water produced by the lengthening or shortening of the copper bar under the action of the heat is indicated.

A Hundred-ton Gun.—Sir William Armstrong has nearly completed the first of his hundred-ton guns for the Italian government. It will be bored to 17 inch calibre, as originally inteuded, and polygrooved, the projectile being rotated by a sort of gas-check at the base.

SCIENTIFIC PROGRESS.

The "Man-root" of Colorado.

Thomas Meehan, the well known horticultural writer to the *Independent* an account of a wonderful Colorado plant. He says:

Once, in Colorado, I came un a convolvulus, or "morning glory," with wine-glass shaped and wine-colored flowers—but a "vine," but a bush, about a foot ur so over. Seed was not ripe, so I tried to get a root; but in no case could I get one out of the ground. This is all I knew. But here at the Centeunial I find the "man-root" of Colorado—the full size and stature of a men—*fifty eight* inches long! And I am told the account of its digging up. First two men, a half a day, with pick, shovel and crowbar; but the plant not out. The next half day so spent; and still no root. Next day the men were sent out with orders not to return without it; and then it came, and such a root as we see! Here is a small spray in my herburium—*Ipomœa leptophylla;* but I never dreamed of its having such a history as this. Most plants send their leaves and branches into the air, the herbaceous parts fall annually, and the trunk increases in size; but here the increase is all, from year to year, under the ground—a trunk like a small palm or tree-fern, crowned every year hy about 18 inches of foliage, all we see, and in ignorance of the great work going on below. We have something like it in the East. The *Ceanothus Americanus* (the New Jersey tea) and the "briar" (*Smilax rotundifolia*) have herbaceous tops, dying back annually, and yet with roots increasing from year to year, and finally making good-sized underground trunks. But this Colorado "man-root" beats them all.

Salt in the Sea.—Professor Chapman, of University College, Toronto, has published an interesting paper on the "purpose" of the saltness of sea water. After giving reasons why he does not accept the usually received opinions, he urges the theory that the object is to regulate evaporation. If any temporary cause renders the amount of saline matter in the sea above its normal value, eveporation goes on more and more slowly. If the value he depreciated by the addition of fresh water in undue excess, the evaporating power is the more and more increased. He gives the results of various experiments in reference to evaporation on weighed quantities of ordinary rain water, and water holding in solution 2.6 per cent. of salt. The excess of loss uf the rain water compered with the salt solution was, for the first 24 hours, 0.54 per cent.; at the close of 48 hours, 1.46 per cent.; and so on in an increasing ratio.

Constitution of the Sun.—M. G. Plante concludes from his experiments that the sun may be coosidered as a hollow electrified globe, full of gases and vepors, and covered with a liquid covering of molten incandescent matter; the wrinkles, or luculi of his surface, result from undulation in this liquefied stratum; the spots are produced by masses of gas and etectrified vapors proceeding from the interior of the orb, penetrating the liquid layer, and giving the edges of the cavities forms which characterize the passage uf positive electricity. The *Faculæ* seem to be a brilliant phase in the evolution of the gaseous masses when they approach the surface before their eruption. The protuberances are formed by the gases themselves issuing from the interior of the sun at a higher temperature, and consequently more luminous than those which form the atmosphere of his surface.

Phenomenal Effect of Rock Boring.—At a late meeting of the Physical and Natural History Society, of Geneva, M. Turrettini, who has to make frequent visits to the boring of the St. Gotherd tunnel, gave an account of a phenomena which is often produced in the granitic mass of the mountain. When the rock is shaken by the explosion of a mine the report is followed, at unequal intervals, hy other spontaneous explosions at considerable distances from the mine hole, of which the cause is unknown, and which are attended with serious results to the workmen. The phenomenon is new, and appears to indicate a kind of tension inherent in the formation of the granite, which, agitated at one point, is transmitted a distance so as suddenly to disengage large fragments of material.

A Shower of Sulphur.—During the late weather, says *Galignani*, the strange phenomenon known as a shower of sulphur was observed in some parts of the Herault. After the rain the leaves of the trees and sides of the road were covered with a yellowish powder resembling sulphur. This curious occurrence happens very rarely in the south uf France, and is only the pollen of conifers carried off by the wind from some pine forest.

Limit of Strain in Iron.—No. 23 of Van Nostrand's Science Series is an essay on the "Fatigue of Metels under Repeated Strains," from the German of Prof. Ludwig Spangenburg, with a preface by S. H. Shreve. "These experiences," Mr. Shreve says, "prove that there is a limit of strain within which iron is practically indestructible, and that that limit is but little over 30,000 lbs. per square inch for the best iron.

Brazilian Gems.

At a recent meeting of the Royal Geographical Society of England, a paper was read hy Mr. T. B. Wither, in which ucte is mede of the precious stones of the country. He says: In the immediate vicinity of the Tioagy, he informs us, there are large deposits of olaya and gravels, in which latter diemonds were discovered abont 30 years ago, and it was this discovery thet led to the formation of the present town, which, thongh the diamond mines are now no longer worked, still gives evidence of proaperity. The working of these diamond mines was abandoned some four years ego, not on account of their exhaustion, but because tha depth which the diamond-yielding stratum had then reached below the surface made their further operstions no longer profitable with the limited resources at the disposal of those interested. Statistics obtained on the spot, and verified where possible from independent sources, and a careful examination of the mine itself, convinced Mr. Wither that though abandoned for the present it is yet capnble of being worked with exceedingly profitable results. On resuming his journey from St. Jeronymo, and having pssed the river of that name, Mr. Withers found that the geological formation underwent a change. In the place of sandstones and porphyries a reddish-brown amygdaloid rock, with its numerous little cavities lined with the green mineral chlorite, forms the body of the hills, and continues to be the dominant formation down to a point some distance below Jatahy, whence down to the Paranapanema sandstone, split up in all directions by dykes and large masses of greenstone, again takes possession. This amygdaloid formetion extends in a southwesterly direction as far as the Jvahy valley, where it assumes a somewhat different character, the cavities in its substence increasing greatly in size, and often containing agates of four and five feet in diameter, which, when broken up, are found to be lined with brilliient and well formed crystels of amethyst and other varieties of quartz.

A New Microscopical Drawing Apparatus—Dr. Holle, Gottingen, has made au instrument the principle of which is to bring into view not tha pencil itself or its reflected image, hut the entire image thrown hy lenses. The eyepiece of the microscope serves also as eyepiece of a telescope bent twice at right angles end having two mirrors. The first (transpareut) is immediately under the eyepiece; the second, under the object-glass of the telescope. The former is very thin (0 2 mm.) that the images of the drawing-pencil, cast by the upper and under sides of the glass plate, may fall on each other. The other mirror is thicker; and between the two is a lens which again reverses the reversed image of the pencil. The microscopio image can thus be seen directly and without fatigue of the eyes. The drawing hand is immediately to the right, and so in the most convenient position. The image is unreversed.

Value in the Violet.—An Italian chemist has just found out that violets yield a very fine blue color, and this is so sensitive to exterior influences, as to render it of considerable value to the analytical chemist. Most people know that one of the best and most delicate tests employed by chemists to ascertain whether a solution is acid or not is to dip into it a piece of blue litmus paper, which at once reddens if tho least trace of acidity exists. In like manner the reddened litmus paper may be employed in searching for alkalies, for the paper returns to a blue tint on coming in contact with these. The coloring principle of the violet and iris is found to be more delicate still than litmus, and for this reason we may expect soon to see phyllocyanin—for so the new color is called—introduced into all our laboratories.

Eucalyptus Leaves and Oil.—In the *Archiv der Pharmacie*, Dr. I. Homeyer has a paper on the leaves of the eucalyptus globulus and their etherial oil. The paper is, first, a description of a microscopical and micro-chemical examination of the leaves. Secondly, a chemical examination of their oil leeds the writer to the conclusion that it is a mixture, containing: 1st, a terpene boiling from 150-151 deg.; 2d, another terpene boiling from 172 185 deg.; 3d, cymol; 4th, an oxidized substance which stands in a simple relation to cymol, and which has the formula $C^{10}H^{14}O$, or $C^{10}H^{16}O$, probably the latter. Dr. G. Vulpius has an essay in which the planting of this kind of trees is recommended, because the oil, having a tendency to produce ozone like turpentine, is thought to be conducive to health.

Ammonia in Rain.—About 4,590,000 cubic metres of rain fell over Paris in 29 days during the recent floods, and an examination of samples led to the estimate that 9,000 kilogrammes (2.2 pounds each) of ammonia were washed down with it, containing sufficient nitrogen for a forest that would cover the whole uf Paris. The question has often been raised whence plents get their nitrogen, and the above figures help to explain it. The rain was also estimated to contain 88,000 kilogrammes of mineral substance, amongst them being globules of iron of meteoric origin.

Metrical System in Sweden.—On May 3d the Swedish Diet voted the adoption of the metrical system with the French nomenclature. Its obligatory use is to date from 1889. The question has been under discussion more than 20 years. It was first brought forward in 1852; the motion was renewed in 1862, and again last year, when it was taken into consideration with the final result as above.

The Mining Share Market.

The depression in stocks has been more than nsually marked dnring the past week. Contradictory rnmors affecting the bonanza stocks have made the market somewhat variable, bnt the bears seem to have had the best of the sitnation. The daily press seems divided in opinion on the snbject of the merits of these mines, and interviews with leading operators are in order. Several of these have appeared, but the pnblic seem none the wiser for them, so varying are the statements. Some say the honanza is nearly worked out; others that it is as good as ever. Dnring the latter part of lsst week and the first part of this the market was in a very depressed condition and the honanza as well as other stocks, as may be seen by our tables, were at "bedrock". Dnring Wednesday, bowever, tbey rallied somewhst, although Thnrsday morning's ssles showed rather a falling off from Wednesday's prices.

There are a good many theories as to the canse of the "decline and fall," more in fact thsn we have spsce even to ennmerate. Whether the decline was the resnlt of a well directed bear movement or simply a lack of confidence of the pnblio we bave no means of knowing. Witb regard to the reports which have appeared in one of our sensational daily papers, Colonel Fair, of the "bonanzs firm," totslly denies tbem. He says that no work has been done for five montbs on the 1500-foot level of the California, and that the 1700-foot level of the Ophir has been flooded since the October fire. Tbe winzes from the 1500-foot level of the California and Consolidated Virginia, he states, are in rich ore. He attributes the efforts of the bears to disparage the mines to their fear of being cinched in stocks.

The decline in silver will no doubt seriously injure tbe silver mining interests of tbe country, and Nevada must natnrally be the first to snffer. We are beginning already to feel the evil effects of the present heavy discount on this metal.

Several important elections of mining companies took place this week. The most prominent wss that of the Savage, over which there has been snch a fight. There were 99,668 shsres represented. The following were the officers elected Trustees: James R. Keene, Henry Keene, John W. Coleman, S Steinhart and Thomaa H. Williams. Henry Keene was elected President, and E. B. Holmes, Secretary. Thns ends the great contest over Savage, which has heen the talk of the street for a month past.

The Yellow Jacket mining company held their election at Gold Hill, and elected as Trustees Thos. G. Taylor (President and Snperintendent), James G. Fair, F. A. Tritte, George A. King and D. L. Bliss. An assessment of $1 per share, amonnting to $120,000, wss levied jnst after the election, the second tax on the new stock, and the 23d assessment since the opening of the mine, aggregating $2,598,000, against $2,184,000 dividends.

The struggle between the dissatisfied stockholders of the Newark mine resulted in an election of an entirely new Board of Trustees, said to be in the interest of the ontsiders and composed as follows: A. H. Gazzli (President), I. Weightman, Joseph Warbnrton, T. B. Smithson and Joseph Naphtaly; and J. A. Fairweather was elected Secretary. There were nearly 18,000 shares of the capital stock voted by the snccessfnl party, the late management making no attempt at opposition.

There is dissstisfaction among the stockholders of the Picton mine, and a movement is on foot to oust the present controllers of the company.

The assessment of the North Chipman mining company, levied March 3d, 1866, haa been declared void by the Fifteenth District Court.

There was no session this (Thursday) afternoon, of the San Francisco Board, the body having adjourned in respect to the memory of the late Jas. H. Latham, who was a member at the time of his death.

THE House has granted a pension of $50 per month to the widow of General Custer.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior in proximity to the mines mentioned.

California.

AMADOR.

FIDDLETOWN MINING NOTES.—Amador *Ledger*, July 15: The period of inactivity has overtaken this prosperous mining camp. The noise of the giants has ceased, the supply of water having failed. The big company—the American Flat—was compelled to suspend hydraulicing on Saturday last. Considerable work, however, is still being done in drifting. We are informed that negotiations are pending for the erection of a ten-stamp mill. A large quantity of cement is met with in this neighborhood, which contains considerable gold. It cannot be worked to advantage by sluicing, and therefore a small mill is to be put up forthwith to reduce it. Should the experiment come up to the expectations, several mills will be running in a short time. The citizens of Fiddletown look forward to a season of great activity next fall.

TO BE STARTED UP.—It is currently reported that arrangements are now being made to commence work on the Hazard mine, on the great mother lode, between the Bunker Hill and Gover mines. A. Hayward, we believe, owns a considerable interest in the property, and it is in consequence of this influence that work is to be resumed at an early day. All the mines in the vicinity which are being worked at present are paying well.

THE COMPANY'S GRAVEL MINE.—The Amador canal company continue to prosecute work upon their gravel mine at Humbug Hill. They recently cleaned up one of the boxes, to put in a new one, and realized some $600 or $700. They have not reached the most auriferous part of the claim yet. No general clean-up will be made until toward the close of summer.

BUTTE.

AT WORK.—Oroville *Mercury*, July 14: The ten-stamp quartz mill on Roberts claim started up a few days ago, and everything about it runs as smoothly as any one could wish. The ledge is one of the richest in the county, though it pays only in spots. When one of these paying streaks is reached, gold is taken out in abundance for a short time.

ELECTRIC MINE.—We learn that a new superintendent has been employed, and that work is progressing rapidly in the tunnel with a prospect of soon reaching the lead. They have a splendid mill that will do good work.

FLEA VALLEY COMPANY.—From Daniel Hilton, one of the directors of the Flea Valley company, we learn that about 100 men are at work on the ditch. The company's saw mill is located in Flea valley, beyond Yankee Hill. A V flume is being built from there to the West branch of the North fork, and will be 15 miles in length. A large part of it has been completed. From there to Pence's, a ditch capable of carrying 3,000 inches of water is being dug. And on this ditch are the 100 men at work with a prospect of being done about the first of November. It will be seven miles from where the water is taken out to the place where the dump will be. This water will be of no small value at this point, as it is in the vicinity of several very valuable mines that greatly need it to carry on operations. Situated as the mill is, in one of the best timbered sections of Butte county, this piece of property is one of the most valuable in the State. It has a very large country to supply with timber, and will save to the farmers a distance of 20 miles' travel over a rough and hilly country.

CALAVERAS.

QUAKER CITY MINE.—Calaveras *Chronicle*, July 15: A 5 ft ledge of fair milling ore has been struck in the Quaker City quartz mine, 20 feet from the shaft, in the 200-ft level. The quartz is so excessively hard that the level is to be diverged from and run parallel with it, prospecting of the vein being done by cross-cutting at intervals. Mr. Macnevin, general superintendent, informs us that he intends driving the level the entire length of the ore chute before putting up milling machinery.

UTICA COUNTRY MINING JOTS.—The new mill being erected on the Josephine, at West Point, will be ready to run on the first of August. Large quantities of high grade ore continue to be taken from the mine. A wide ledge of good ore has been struck in the 300-ft north level of the Mica Rica, 50 feet from the shaft. Indications that it is an extensive permanent chute of ore are favorable. We have it from a pretty reliable source that all claims against the San Bruno mine, at Mosquito, will be paid up and work resumed within 10 days.

MINE SOLD.—The Mt. Tmolus quartz mine, located in Jesus Maria district, formerly owned by Messrs. Rigney, Lefoy and Tynan, has been sold to a company of San Jose capitalists. We cannot speak authoritatively regarding the sum for which the mine was sold, but common report fixes it at $6,000—$4 000 down and the balance at some future time. We understand that the new proprietors will immediately commence active operations, having already, in fact, let a contract for sinking the shaft 50 feet deeper.

THE LAMPHEAR MINE.—Active preparations are being made for sinking the shaft on the Lamphear quartz mine, near town, 100 feet deeper. For the purpose of keeping the mine free of water and facilitating sinking, a 6 inch Cornish pump is to be put into the shaft. The pump is to be run independent of the hoisting works, a hurdy-gurdy now being erected to furnish the necessary power. The frame-work for the reception of the water wheel is already completed and the pump is on the ground.

EL DORADO.

QUARTZ.—We have been permitted to examine a few specimens of ore from the Blue lead at Spanish Flat. This ledge is owned by Varozza, Witmer and others. Edwards and Pasqui have a contract to sink a shaft on the ledge from the old tunnel. They are now down about 60 feet, where they have a ledge from 5½ to 6 feet wide. Assays of the ore has ranged from $80 to $100 per ton. There are now about 100 tons of ore on the dump. The samples exhibited to us sustain the above reports as to the quality of the ore.

FRESNO.

QUARTZ.—Fresno *Expositor*, July 12: T. J. Dunlap left at this office last week a specimen of quartz taken from the Confidence mine at a depth of about 90 ft. The rock appears more solid than that taken from near the surface, and the gold seems to be more generally diffused through the rock. The rock carries considerable sulphurets and some silver. The ledge now shows a width of about 9 feet.

INYO.

THE DEFIANCE.—Coso *Mining News*, July 15: Work on this mine has been continuously progressing. The main incline is now down from the mouth of the main tunnel 160 feet. The dip of the incline for the first 100 feet is about 32 degrees, and the dip of the other 60 is about 45 degrees. At the bottom of this incline a vein has been struck and breaking into it shows very fine carbonate ore, but whether this is the foot wall of ledge No. 2, or another blind vein lying between ledge No. 1 and ledge No. 2, we are unable as yet to determine; however, it proves that the ore not only continues down but is richer as depth is obtained. From the bottom of said shaft to the surface of ledge No 2 (admitting the ore in the bottom of this shaft to be on ledge No. 2) it is 180 feet perpendicular. This, we imagine, proves the permanency of the Defiance beyond a question, but when we state that the ore is more concentrated and richer, we only assert an absolute fact. The north drift or tunnel running to tap the immense ore body proved by north incline shaft, is now in ore, showing the same general characteristics as that in vein No. 2, carbonate and galena. There is enough ore in sight in ledges Nos. 1 and 2 at present to keep both furnaces running for an indefinite period. The drift running north on vein No. 3 is now in 50 feet, and is being stoped 50 feet in hight from the floor of the main tunnel, with the same class of ore on the roof of stope. This is the most remarkable vein of the series, being of a fine yellow chloride and carbonate, and more concentrated than veins 1 and 2. The ore is much richer, as the bullion now being extracted from it shows the true ring of the metal.

LOS ANGELES.

COAL AND OIL.—Reports from the San Fernando oil and coal regions are very encouraging. In addition to the late flattering oil prospects, a vein of coal has just been discovered, which promises to prove valuable. This coal mine was found by Mr. Brophy some months ago, but until within a few weeks past it remained unprospected. Lately, however, parties have sunk some 15 or 20 feet on the vein, and find the seam to increase in width and the coal in quality. The close proximity of this mine to the Southern Pacific railroad will give its products increased value. The oil fever is increasing as the prospects become more encouraging. Mr. Michael Brophy, who owns large land interests in the oil region, informs us that two mines have been placed on the market in San Francisco, at $150,000 each, and the indications are that the stock will sell readily. The well in which a flowing stream was struck some weeks ago continues to pour forth a steady volume of oil, and old miners are confident other wells of equal or greater power will soon be struck.

NEVADA.

GRAVEL.—*Foothill Tidings*, July 15: A prospect shaft is being sunk on the northwest corner of the old Weare place, Alta hill, with the expectation of striking a pay channel of the old river bed known to be somewhere in the vicinity. We shall watch this work with much interest, as a new development on the Alta or its tributaries would be a grand thing for Grass Valley.

GOOD MINE.—We are glad to learn that the Yuba mine, near Washington, in this county, which was bought by a company in this place, the Messrs. Coleman being the principal owners, about a year ago for the sum of $40,000, has prospered so well under the efficient management of the superintendent, Mr. George Lord, that an offer was recently made by responsible parties from San Francisco, of $220,000, or at the rate of $55 per share. The owners, we understand, think there will be no trouble in realizing that sum in a year or two and then leave the mine worth several times as much.

HOWARD HILL MINE.—We are glad to say that it is now almost certain that work on the Howard Hill mine will be resumed in about two weeks. All the indebtedness of the mine has been settled up and everything has been put in shape ready for the resumption of business.

RICH STRIKE.—Placer *Argus*, July 15: Tyler and Lawler have struck a quartz ledge about a mile and a half west of Clipper Gap, which, from accounts, equals in richness the best strikes of early days. The ledge is only a few inches thick, thoroughly decomposed, and shows free gold all through it. They have sunk down about 25 feet, and all the rock thus far taken out has yielded from $1 to $50 to the pan. If this holds out the boys need nothing better.

MINING ITEMS.—At the Eclipse mine work is progressing finely. The ledge, we understand, holds out well in size, and the character of the ore is good. The crushings thus far have been satisfactorily remunerative. The Booth mine, which was shut down some time ago, has been worked some recently by William Werry, who met with encouragement. The company propose to start the mine up themselves within a short time. The St. Patrick company, at the Crater mine, are moving steadily along at about the same old rate; getting out good rock, and cleaning up at the end of every month lots of gold. The Julian mine, on Jenny Lind flat, below Newcastle, is not doing so much work as usual just now, owing to prevailing indisposition among the hands. The cause is not known, unless it be the extreme change in the weather, but nearly every other man employed at the mine was a few days ago suffering some complaint or other. The mine itself is looking very fine. The main shaft is down about 300 feet, and the lead at the bottom, which averages about two and a half feet thick, is richer than it has been at any point between that and the surface. A crushing from rock taken from the new air shaft being sunk about 300 feet north to connect with the 140-ft level, paid at least a third more than the best ore taken out of the main shaft, which is another encouraging indication.

PLUMAS.

MINING ITEMS.—The Franklin company, on Willow creek, are making arrangements for their machinery, and will soon be at work again in their shaft. Surveyor Hendel, of La Porte, has, during the past week, been making a survey of the underground work of the Crescent mine. Work on the Buchanan ledge, near Indian valley, is soon to commence. Numerous mining locations are being made in Plumas these days. A lot of rock from the New York ledge, near Greenville, owned by Whitlock & Co., recently crushed in the Lone Star mill, paid over $15 per ton. The East Branch company's mine, below Shoo Fly, is prospecting splendidly. The superintendent, J. W. Smith, has gone below for a short time. Meyfert & Bell have located 40 acres of mineral land near Nigger gulch.

SAN BENITO.

QUICKSILVER.—Salinas *Index*, July 13: We had a call the first of this week from Mr. George Shriver, of the Salinas quicksilver mine, situated in San Benito county, about 40 miles from this city. He informs us that their tunnel is in 125 feet, and they have cut the lead and are following it. In the tunnel they struck a solid vein of antimony, 12 inches thick. Veins of quicksilver run through the antimony and all over the face of the tunnel. Mr. Shriver is jubilant over the prospects of his company, and thinks they will develop a quicksilver bonanza of huge proportions. In close proximity to the Salinas mine is the Consolidated Woader, which is yielding considerable ore of good quality, the owners of which have the brick burned for the construction of a smelting furnace.

TUOLUMNE.

THE BEMINGTON GRAVEL MINE.—Tuolumne *Independent*, July 15: This claim, recently purchased of James Brown and Cie Johnson, for $3,000 by San Francisco parties, is situated near Yankee hill, above the old Shanghai mine. The claim covers 20 acres, and has been prospected 40 feet deep, with no bottom to the gravel, which prospects well. The new owners are now running a race to the claim, some 600 or 700 feet, which will tap the deposit 80 feet deep. They are putting in a three-foot flume, with a fall of eight inches to a 16-foot box. They have just received 900 feet of 11-inch pipe, No. 14 iron, which will be used to convey water for the hydraulic. A part of the pipe at the head will be 18-inch. They will use a "little giant," with 300 inches of water, to be furnished by the Tuolumne water company. Some dozen men are at work getting the claim ready for washing, which will probably be in two weeks—in the race. Undercurrents and all the latest improvements in hydraulic mining will be put in as the work progresses. We look upon this enterprise as opening a new era in Tuolumne county mining. We have often called attention to the large deposits of gravel known to exist above Columbia, and are glad to notice that a move has been made to work some of them. At the Philadelphia diggings and vicinity, are hundreds of acres of these deposits, which only await a little capital to open immense sources of wealth.

A RICH quartz mine has been discovered near Yankee hill, one-quarter of a mile distant from and supposed to be an extension of the old Shanghai lode. The croppings are exceedingly rich in free gold. Mr. Remington, the owner, will organize a company to develop the lode.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—Gold Hill *News*, July 13: Sinking the main shaft to connect with the upraise from the 1650-ft level is going rapidly ahead. The downward extension of the shaft, along with other needed repairs, has greatly interfered with the extraction of ore during the past week. The main north drift on the 1700-ft level is steadily advancing, the face in good running ground. The improvement of the air on that level by the use of the fan will be sufficient to soon admit of cross-cutting the ledge in that portion of the mine. The draft of air through the main drift, connecting with the C. & C. shaft on the 1500-ft level, is also greatly benefiting the ventilation in that part of the mine. At the C. & C. shaft a very serious breakage occurred during the first part of the week. The pump-rod parted near the top of the shaft, letting the piston back with such force as to burst the cylinder-heads in. New heads were immediately ordered, and the damage will be repaired in a very few more days. In the meantime the water is being kept down in the shaft by a steady use of the hailing tanks. Sinking the shaft will be resumed as soon as the water is drained.

CALIFORNIA.—Daily yield, 700 tons of ore. The ore breasts are looking splendidly and are yielding rich ore. The mine in fact is showing splendidly throughout. All the winzes and air openings have been repaired and enlarged up to the 1300 ft level, so as to give as great a circulation of air as possible. A portion of the ore extracted is being hoisted to the surface through the Ophir shaft.

BULLION.—Slow progress is being made in the northeast Alpha drift, on the 2000-ft level, on account of great heat. The drift will have 60 or 80 feet yet to run to connect with the north drift of the Imperial mine, so as to get the needed circulation of air. The upraise from the 1700-ft level has not yet made the connection with the winze now being sunk from the 1400-ft level, although the workmen are very close together and are liable to complete the connection at almost any moment. As soon as this connection is made it will complete the ventilation from the 1700 up to the 800-ft level. As soon as this connection is completed and the 1700-ft level is ventilated, the prospecting of that portion of the mine can be resumed at once.

YELLOW JACKET.—The east winze below the 1950 ft level is down 100 feet, or to the 2040-ft level. It is the intention to start a drift from each winze to connect the two for ventilation purposes at the very earliest moment possible. The two winzes are about 150 feet apart.

SIERRA NEVADA.—Sinking the main shaft is making the usual excellent progress, the bottom still in porphyry mixed with seams of quartz and clay highly impregnated with pyrites of iron and sulphur.

AMAZON & GLASGOW.—The combination shaft is being steadily crowded downward at a very rapid rate of speed, considering the character of the rock. It is now down 352 feet. At the depth of 400 feet it is the intention to open another station and prospect the ore vein. It is confidently believed by experts that a concentration of the rich sulphuret ore struck on the third level will be found when a greater depth is attained, and a good paying body of ore developed. This shaft is developing both mines. Some very fine seams of quartz and ore are occasionally encountered in the bottom of the shaft.

JUSTICE.—Daily yield, 70 tons of ore per day. The ore breasts are looking well and yielding good ore. The Woodville mill started up on ore from the mine during the fore part of the week. It has a crushing capacity of about 25 tons per day. The Shearman and Excelsior mills are also kept busy crushing the ore. The developements both north and south, on the 800-ft level, are of the most favorable character.

OPHIR.—Daily yield, 280 tons of ore, keeping the mills steadily running. The ore breasts on the 1600-ft level are showing well and yielding the usual amount of good ore.

UTAH.—Sinking the shaft is making better progress than it has done before for some months. The rock in the bottom is still quite hard, but bisste out well. The flow of water is giving much less trouble. The shaft is down 790 feet, or 390 feet below the 400-ft level.

SUPERIOR.—A burst of water flooded the shaft for two or three days during the first portion of the week, stopping the sinking and concentrating the full use of the machinery in its extraction. Last evening the water had been again drained sufficiently for the men to resume work in the bottom of the shaft, which had the appearance of being nearly the full size, in quartz of the finest description. This begins to look as if the shaft will soon cut the ore vein.

JULIA.—The main south drift on the 1500-ft level is looking better every day. The face of the main south drift on the 1600 ft level is also showing much better. The quartz and ore encountered are of better quality, and it seems almost certain now that by the time the drift has reached as far south as where the quartz and ore is found on the level above, a good paying mine will be opened.

BADGER.—Nothing is yet doing in the shaft, on account of the strong flow of water recently struck. This, however, will soon be remedied, as the company are preparing to put up first-class hoisting works, and pumping machinery of sufficient power to drain the water and permit the prosecution of the development of the mine without further delay.

NORTH CON. VIRGINIA.—The guides have been finished in the shaft and the water drained, ready to resume sinking. The pump stations are completed, ready to receive the pumps and hobs. The stone foundations for the engine are finished, and the placing of the machinery has been commenced. The drain tunnel has yet about 230 feet to run to connect with the shaft.

WEST BELCHER.—The extraction of ore has been commenced in good earnest from the 340-ft level. The assays of ore are excellent, varying from $50 to $70 per ton. The ore bressts are looking well and promise a good yield. It is the intention to commence milling the ore about the 15th of the present month. The ore breasts are about 20 feet in width, and are yielding about 40 tons per day of ore. The Vivian mill on the Carson river, has been engaged to crush the ore.

SAVAGE.—The old pumps and pump columns are being rapidly taken from the shaft and the new ones lowered into their places. The huge pumping engine will soon be ready to start up.

BELCHER.—The usual amount of ore is being extracted, and the ore breasts show but little if any change. The erection of the new pumping machinery at the air shaft is making the usual steady progress.

CALEDONIA.—The water was drained and the bottom of the shaft reached a day or two ago, and the sinking resumed in good earnest, when the water again poured in at the bottom at a rate so fearful that the sinking was once more suspended. It is, however, again under control.

OVERMAN.—Sinking the shaft has been resumed and is making fair progress. The foundations for the new pumping engine are fast approaching completion.

WARD.—Sinking the shaft is going ahead at the rate of four feet per day. The Burleigh drilling machine and air compressor for running it has arrived on the ground and is being set up ready to run.

IMPERIAL CONSOLIDATED.—The north winze is down a distance of 112 feet, the bottom still in ore of a fine character. The south winze has reached the level of the Yellow Jacket 1940-ft level, and a drift is about being started to connect with the Yellow Jacket works at that point.

DAYTON.—Sinking the main shaft is going steadily forward, the bottom being in good hiasting ground. The flow of water is still strong.

TAHOE.—Sinking the combination shaft on the south line of the Lady Bryan mine is being pushed ahead with all the vigor possible.

SUCCOA.—During the first portion of the week the water was drained from the shaft and the old pumps taken out to make room for the new. The foundations for the new pumping machinery are all well under way.

ALTA.—Nearly the whole of the new machinery is now on the ground, and most of it is in place ready for use.

CHOLLAS POTOSI.—Daily yield, 75 tons of ore, the assay value of which is $33 per ton. Sinking the main incline is progressing at the rate of two feet per day. Sinking the Combination shaft is going steadily ahead. The new hoisting and pumping machinery is being rapidly placed in position, ready for work.

CROWN POINT.—Sinking the main incline is being pushed vigorously forward, the bottom in hard blasting rock. The main south drift on the 1700-ft level is still advancing, the face in low grade ore.

PHIL. SHERIDAN.—Sinking the shaft is making steady progress notwithstanding a strong flow of water at the bottom. This flow of water takes up much of the use of the machinery in draining it and makes the task of sinking much more laborious than it would otherwise be. The shaft is now down 232 feet.

ROCK ISLAND.—The pumps are gradually gaining on the flow of water, which appears to be steadily lessening.

NIAGARA.—Sinking the main incline is progressing at the rate of two and a half feet per day, the bottom in soft porphyry, carrying heavy seams of clay, with some quartz and ore of a very encouraging description.

EUROPA.—Driving the north drift on the 500-ft level is making excellent progress, the face still in porphyry with occasional streaks of clay.

SILVER HILL.—Sinking the main incline is being pushed vigorously forward, the bottom still in hard blasting rock. It is now down 050 feet.

LADY BRYAN.—Laying the foundation for the new and powerful pumping machinery is making steady progress. Sinking the joint shaft on the line of the Tahoe is making favorable progress.

NEW YORK CONSOLIDATED.—Preparing to get in the pumps. As soon as this is completed, will resume sinking.

FLORIDA.—South drift in clay and quarlz, with bunches and stringers of low grade ore.

COSMOPOLITAN.—North drift going ahead as usual, showing good pay ore in its face.

SUTRO TUNNEL.—Total length of tunnel, 13,758 feet. Face of header in favorable working vein matter. The Ingersoll and Burleigh drills do excellent execution, and the regular weekly advancement is from 00 to 80 feet.

MITCHELL.—Excellent progress is being made sinking the winze, which is now down 87 feet, with the bottom in very promising low grade ore. The ledge is five feet wide, and increases in width.

BALTIMORE AND AMERICAN FLAT.—The north and south drifts on the 1050-ft level are in very favorable ground.

UNION CONSOLIDATED.—The north drift on the 1300-ft level is being steadily advanced, the face still in favorable ledge matter.

NEVADA.—Cross-cut from main south drift still in improving quartz.

BALTIC CONSOLIDATED.—Face of the drift in favorable looking clay and porphyry, with streaks of quartz.

ELY DISTRICT.

LOCAL NEWS.—Pioche *Record*, July 11: During the past week there has been shipped $28,291 in bullion by Wells, Fargo & Co., an increase of $20,000 on the previous week. At the Raymond & Ely mine the same work continues without change of note, and are turning out about the usual amount of ore. In the Meadow Valley, excavations are being made in the mine for the pumps and tanks and also for a hoh pit. The contractors in the American Flag still continue the work of sinking on the main shaft, whilst a small amount of work goes on in the upper levels. Sinking on the main shaft of the Pioche is also going on rapidly, the prospects being flattering. Work at the Alps mine is continued without change, whilst at the mill they are crowded with custom ore that is daily arriving. Work on the Antilica in the cross-cut, is progressing regularly. In the Hunn & Hunt, the owners are pushing the work of extracting ore as rapidly as possible, and with good success. The owners of the Washington & Creole are extracting ore rapidly and shipping the same to the Alps mill for reduction, ten men being employed at the mine. The two smelting furnaces that are to be erected are engaging the attention of business men, by the time chases are soon as they are started, affairs will improve in the camp, as each one will place to work, either directly or indirectly, nearly 200 men, besides the miners who will be engaged in extracting smelting ore. With the erection of these furnaces and the pump of the Meadow Valley startlog to work, we may look for increased prosperity in the camp in mining matters before a great lapse of time.

Montana.

MINING ITEMS.—Helena *Independent*, July 9: The mining ground at the head of Granite gulch, in Madison county, has been surveyed for claimants. Armstrong's smelter at Glendale is doing a splendid business. Mining prospects in Bryant's gulch are reported to be much better than last season. Burton gulch miners have a fine head of water and are taking out good pay. The Epler lode, near Iron Rod, is improving in the quality of its ore. The arastra of Mayne & Wilson, on Cherry creek, is crushing a very fine quality of rock with the best possible results. Heinman's mill at Silver Star started up last week and is doing a fine business. The new quartz discoveries near Missoula are reported to be exceedingly rich. The Chinese are talking about abandoning the Alder gulch placers. A fine head of water is making things lively in the Cedar creek mines. McGovern & Co.'s diggings on Moose creek are turning out well. The placers on French bar are turning out a large quantity of gold dust. The bedrock flume on Clancy creek is working splendidly, and the miners are taking out good pay. The Pioneer ditch is carrying to the miners a regular supply of water. Rocker and Basin gulches are sending in large quantities of gold dust. The mines are much better this year than last season. The Trout creek ditch is giving a regular supply of water, and mining prospects are unusually encouraging. The new bedrock flume in Greenhorn gulch is to have 100 feet pressure. The Wisconsin Gulch mining company have got their bedrock flume nearly completed. Mining operations in Meagle gulch, which were suspended for a while on account of the flood, have been resumed.

Oregon.

EETHER MINE.—Oregon *Sentinel*, July 9: Mr. Wallace one of the owners of the Eether mine, generally known as the "Browning load," was in town on Saturday. He informed us that work was progressing finely and everything looked satisfactory. They have a five-stamp weter mill running, and will soon have a pan to assist it. Its capacity is an average of nine tons a day. The company has expended considerable this spring, in money and labor, in constructing roads from the mine to the mill, about a mile apart, and they are now taking out ore that looks better than any yet crushed. The rock yields about $10 per ton. They expect to do more work, and with much better results, as soon as they get their pans to work and complete more perfect methods of taking out and delivering the ore.

THE Constitution of Colorado prohibits the imprisonment of witnesses in criminal cases. It also provides that no new bill shall be introduced into the Legislature during the last 15 days of a session, and absolutely prohibits all special legislation.

The Centennial Ode.

The following national ode, written for the occasion by Bayard Taylor, was read at the Fonrth of July celebration at the Centennial Exposition:

I.

Sun of the stately Day,
Let Asia into the ehadow drift,
Let Europe bask ln thy ripened ray,
And over the severing ocean lift
A brow of broader splendor!
Give light to the eager eyes
Of the land that waits to behold thee rise;
The gladness of morning lend her,
With the triumph of noon attend her,
And the peace of the vesper skies!
For, lo! ehe cometh now
With hope on the lip and pride on the brow,
Stronger, and dearer, and fairer,
To emile on the love we hear her—
To live, as we dreamed her and eought her,
Liberty'e lateet daughter!
In the clefts of the rocks, in the eecret places,
We found her tracee;
On the hills, in the crash of woods that fall,
We heard her calt;
When the linee of battle broke,
We saw her face in the fiery emoke;
Through toil, and anguish, and desolation,
We followed and found her.
With the grace of a virgin nation
As a sacred zone around her.
Who shall r joice
With a righteoue voice,
Far heard through the ages, if not she?
For the menace ie dumb that defied her,
The donht le eesd that denied her,
And she etands acknowledged and strong and free.

II.

Ah, hark! the eolemn undertone
On every wind of human story blown.
A large divinely-molded Fate
Questions the right and purpose of a State,
And in its plan euhlime
Our eras are the dust of Time.
The far-off Yesterday of Power
Creepe back with etealthy feet,
Invades the lordship of the honr,
And at a banqnet takes the unbidden seat.
From all unchronicled and silent ages
Before the Future first h-got the Past,
Till History dared, at last,
To write eternal words on granite pages:
From Egypt'e tawny drift, and Aesur'e mound,
And where, uplifted, while and far,
Earth highest yearns to meet a star,
And man his manhood hy the Ganges found,
Imperial heads, of old millennial sway,
And still by some pale eplendor crowned,
Chill as a corpse-light in our full-orbed day,
In ghostly grandenr riee
And say, through stony lips and vacant eyes:
"Thou that assertest freedom, power and fame,
Declare to ne thy claim!"

III.

On the shores of a Continent oset,
She won the Invlolate eoil
By loss of heirdom of all ths Paet,
And faith in the royal right of Toil!
She planted homes on the ss vage eod,
Into the wilderness lone
She walked with fesrlese feet.
In her hand the dlvining rod,
Till the veins of the mountaine heat
With fire of metal and force of stone!
She set the speed of the river-head
To tnrn the mills of her bread;
She drove her plowehare deep
Through the prairie's thousand-centuried sleep;
To the South, and West, and North,
She called Pathfinder forth,
Her faithful and eole companion,
Where the finished Sierra, snowy-starred,
Her way to the sunset harred.
And the nameless rivers in thnnder and foam
Channeled the terrible canon!
Nor paused, till her uttermost home
Was built, in the emile of a softer eky
And the glory of beanty still to he,
Where the haunted waves of Asia die
On the strand of the world-wide sea!

IV.

The race, in conquering,
Some fierce Titantic joy of conqnest knows;
Whether in veine of serf or king,
Onr ancient blood heats restless in repose.
Challenge of Nature unsubdned
Awaits not man's defiant answer long;
For hardship, even as wrong,
Provoked the level-eyed heroic mood,
This for herself she did; hut that which lies,
As over earth the skies,
Blending all forms in one benignant glow—
Crowned conscience, tender care,
Justice, that answers every bondman's prayer,
Freedom where faith may lead or thonghts may dare,
The power of minds that know,
Passion of hearts that feel,
Purchased by blood and woe,
Guarded by fire and steel.
Hath she secnred what blazon on her shield,
In the clear Century's light
Shines to the world revealed,
Declaring nobler triumph, horn of right?

V.

Foreseen in the vision of sages,
Foretold when martyrs bled,
She was born of the longing of ages,
By the truth of the noble dead
And the faith of the living fed!
No blood in her lightest veine
Frets at remembered chains,
Nor shame of bondage has bowed her head.
In her form and featuree etill,
The unblenching Puritan will,
Cavalier honor Hnguenot grace,
The Quaker truth and sweetness,
And the strength of the danger-girdled race
Of Holland, blend in a proud completeness.
From the homee of all, where her being began,
She took what she gave to man:
Justice, that knew no station,
Belief, as soul decreed,
Free air for aspiration,
Free force for independent deed
She takes but to give again,
As the sea returne the rivers in rain;
And gathers the chosen of her eeed
From the hunted of every crown and creed.
Her Germany dwells hy a gentle Rhine;
Her Ireland seee the old sunhurst shine;
Her France pursues some dream divine;
Her Norway keeps his mountain pine;
Her Italy waits by the western brine;
And broad-based under all,
Is planted England's oaken-hearted mood,
As rich in fortitude
As e'er went worldward from the island-wall
Fused in her candid light,
To one strong race all races here unite;
Tongues melt in hers, hereditary foemen
Forget their sword and slogan, kith and clan;
'Twss glory, once, to be a Roman;
She makes it glory now to be a man!

VI.

Bow down!
Doff thine Æonian crown!
One hour forget
The glory, and recall the debt;
Make expiation
Of hnmbler mood,
For the pride of thine exultation
O'er peril conquered and strife subdued!
But half the right is wrested
When victory yields her prize,
And half the marrow tested
When old endurance dies.
In the sight of them that love thee,
Bow to the Greater above thee!
He faileth not to smite
The idle ownership of Right,
Nor spares to einews fresh from trial,
And virtue schooled in long denial,
The tests that wait for thee
In larger perile of prosperity.
Here, at the Century's awful ehrine,
Bow to thy Father's God and thine!

VII.

Behold! She bendeth now,
Hnmbling the chaplet of her hundred years;
There is a solemn sweetneee on her brow,
And in her eyes are sacred tears.
Can she forget,
In present joy, the hnrden of her debt,
When for a captive race
She grandly staked and won
The total promise of her power hegun,
And bared her bosom's grace
To the sharp wound that inly torturee yet?
Can ehe forget
The million graves her young devotion eet,
The hande that clasp ahove
From either side, in sad, returning love?
Can she forget,
Here, where the ruler of to-day
The citizen of to-morrow,
And equal thousands, to rejoice and pray
Beside these holy walls are met,
Her birth-cry, mixed of keenest hlles and sorrow?
Where, on July's immortal morn
Held forth the people saw her head
And shouted to the world: "The King ie dead,
But, lo! the Heir ie born!"
When fire of youth, and sober trust of age,
In farmer, soldier, priest, and sage,
Arose and cast npon her
Baptismal garments—never robe so fair
Clad prince in old world air—
Their lives, their fortunes, and their sacred honor!

VIII.

Arise! Recrown thy head
Radiant with blessing of the dead!
Bear from this hallowed place
The prayer that purifies thy lips,
The light of courage that defies eclipse,
The rose of man's new morning on thy face!
Let no iconoclast
Invade the risin« Pantheon of the Past,
To make a blank where Adam stood,
To touch the father'e sheathed and sacred blade,
Spoil crowne on Jefferson and Franklin laid,
Or wash from Freedom's feet the etain of Lincoln's blood.
Hearken, as from that haunted hall
Their voicee call:
"We lived and died for thee;
We greatly dared that thon might'et be;
So from thy children still,
We claim denials which at last fulfill,
And freedom yielded to preserve thee free!
Beside clear-hearted Right
That smiles at Power'e uplifted rod,
Plant duties that requite,
And Order that sustains, upon thy eod,
And stand in stainless might
Above all self, and only lese than God!"

IX.

Here may thy eolemn challenge end,
All-proving fact, and each discordance die
Of donbtful augury,
Or in one choral with the Present blend,
And that half-heard, sweet harmony
Of something nobler that our eons may see!
Though poignant memories hurn
Of days that were, and may again return,
When thy fleet-foot, O Hnntress of the Woode
The slippery brink eef danger knew,
And dim the eyesight grew
That was so sure in thine own solitudes—
Yet stays come richer sense
Won from the mixture of thine elements,
To guide the vagrant scheme,
And winnow truth from each conflicting dream.
Yet in thy blood shall live
Some force misspent, some essence primitive
To seize the highest use of things;
For Fate, to mold thee to her plan,
Denied the food of kinge,
Withheld the udder and the orchard fruits,
Fed thee with savage roote,
And force t thy harsher milk from harren breasts of man!

X.

O sacred woman—form
Of the first people's need and passion wrought—
No thin, pale ghost of thought,
But fair as morning and as heart'e blood warm,
Wearing thy priestly tiar on Judah'e hills,
Clear-eyed beneath Athen's helm of gold;
Or from Rome's central seat
Hearing the pnlses of the continente beat
In thnnder where her legions rolled;
Compact of high heroic hearte and wills,
Whose being circles all
The selfees aime of men, and all fulfille;
Thyself not free, so long as one is thrall;
Goddess, that as a nation lives,
And as a nation dies,
That for her children as a man defies,
And to her children as a mother gives,
Take our fresh fealty now!
No more a Chieftainess, with wampum-zone
And feature-cinctured brow;
No more a new Britannia, grown
To spread an equal oanner to the breeze,
And lift thy trident o'er the double eeas;
But with unborrowed crest,
In thine own native beauty dressed,
The front of pure command, the unflinching eye, thine own

XI.

Look np, look forth and on!
There'e light in the dawning eky;
The clouds are parting, the night is gone:
Prepare for the work of the day!
Fallow thy pastures lie
And far thy shepherds stray,
And the fields of thy vast domain
Are waiting for purer seed
Of knowledge, desire and deed,
For keener sunehine and mellower rain.
But keep thy garments pure;
Pluck them back with the old disdain
From the touch of the hands that stain!
So shall thy etrength endure.
Transmute into good the gold of gain,
Compel to beauty thy rude powere,
Till the hounty of coming hours
Shall plant on thy fields apart,
With the oak of toil, the rose of art.
Be watchful, and keep us so;
Be strong, and fear no foe;
Be just and the world shall know!
With the eame love love us as we give;
And the day shall never come,
That finds ue weak or dumb
To join and smite and cry
In the great task, for thee to die,
And the greater task, for thee to live!

Oregon's Representative Mine.

A correspondent of the *Oregonian* writing from Bsker city desoribes the Virtue mine, which is sitnsted about eight miles from that town, as follows:

One is surprised at the amount of work done and the improvements which sre being accomplished. Mr. Rockafellow and others discovered this mine in 1863. The shafts now are snnk to 500 feet in depth and the workings are hy five levels. The present ore is heing taken out from hetween the second, third and fonrth levels principally. One hundred thonsand dollars in hullion have been realized in the six months of the present year. The main shaft, the mouth of which opens into the new building where the hoisting works sre to he erected, is substantisily and admirably timhered down to the lowest level. It presents an opening eight feet hy four and a half feet in extent. It is divided or partitioned, so that on one side there is a conveniont ladder way, where ascent or descent is made easy, so that free communication with the levels is maintained while the ore hnokets are rising and descending.

Down this shatt went your correspondent to the third level, where the steam machinery is at work, to keep the lower levels free from obstruction hy water, and, hy the way, all the water that is pnmped from the mine is utilized hy the stamp mill, which runs 20 stamps. Furnished with a lighted candle we proceeded along the third level to its hreast, a distance of some 400 feet. It was something new and exciting, hardly to he described. Cara filled with ore passing yon, while you crouched in a little recess, to permit them to do so. The stoping ont in the fourth level in one place had made communication with the npper one so that you conld look down and see the men at work. The vein matter, or the lode, more properly speaking, perhaps, inclines considerably, dipping towards the west. The third level communicates with a tnnnel 580 feet long, through which the ore is conveyed hy cars to the stamp mill.

When the new hoisting works are completed all the ore will he taken ont at the main shaft, and the stamp mill moved to a more convenient locality. At present it is too far from the mine. The new building, 48 feet by 60 feet, for the hoisting works, is a substantial structure, containing the furnace, hnilt of stone, the hoilers, engine and necessary machinery for the purpose intended. The great expense attending the transportation of shoes for the mill and other heavy pieces of casting, which frequently have to be replsced, hsve determined the owners of the mine to erect a foundry of their own, which will soon he in operation, on the site of the old Ruckel stamp mill in Baker city, where there is an excellent water power. At present there are employed in and about the mine some sixty men. The mining force is composed of forty men operating day and night. The chief ownership of the Virtoe mine rests with J. W. Virtne, Esq., of this city, and a Mr. Gray, of San Francisco. The enterprise and pnsh of these gentlemen as displayed in the Virtne mine, entiile them to he successful and prosperous.

Arizona Mines.

A correspondent of the Santa Barhara *Index*, who is now traveling through the monntains of Arizona, writes an interesting letter to that paper, from which we extract the following:

"This little town of Greenwood is 245 miles up the Colorsdo river from Yuma, and 40 miles east of Aubrey, on the river. It is the site of the Greenwood mill, owned by the Senator and Alta consolidated mining company, whose mines the Senator and Alta, commonly known as the McCracken mine, is 12 miles west at McCracken hill, or mountain. Greenwood is in the beautiful little valley of the Sandy, which comes in from the north, and which uniting with the Santa Msria, some 15 miles south, forms the Bill Williams fork of the Colorado. It is here a fine, clear little rivulet which, like most of the streams of Arizona, sinks at places in the deep sandy hed, and after a few miles agsin reappears, running for a distance and then agsin sinking. The same is also trne of the Santa Maria, and slso of Bill Williams fork. There is a population of about 100 here all told—three small stores, the mill, blacksmith's shop and one public eating honse. Up the valley a few miles are a half dozen or more ranchoa or farm, which can he irrigated and capahle of producing fine crops of grain, frnit and vegetahles of all kinds. The olimate is good and sickneaa almost unknown; in trnth the climate of the monntain region of Arizona and the Colorado river region is unsurpassed. The water of the Sandy is excellent and the water from the few small streams and aprings here and thers in the mountains is pure and good generally. The oonntry to the north for 100 miles is all a rioh mineral region, and to the east, south and west, are some of the best mines yet opened in the Territory. To the sonthwest some 18 miles is the Johnson mine, hut partially opened, which was lately sold to a Boston company for $30,000 cash. To the north of the Johnson mine some 10 miles is the Potts mine, which is partially opened with excellent prospects of a large and rich vein.

Twelve miles west of Greenwood, and six north of the Potts mine, is the celebrated McCracken mine, now known as the Senator and Alta consolidated, which is the best developed of any in the Territory, although it was discovered only 21 months since. It is incorporated in California and is now heing put in good shape for working, and 25 miners can take ont a daily snpply of ore to run a 40 stamp mill for many years to come. It is opened by shafts over 600 feet, the main one heing 367 feet deep, and has 4 tnunels which aggregate 1,100 feet in length. The hody of ore at the 155, 255 and 355 foot levels has been worked in places to a width of from 25 to over 42 feet in width, and the hanging and foot walls in no one place reached. The actnsl width of the ore is yet wholly unknown, hut the qnantity is enormons. One peculiarity of this mine is the total absence of all qnartz, in which respect it differs from all others. The formation is spar, and the conntry rock is granite. The ore is of a dark color mostly, and to the casual observer presents the sppearsnce of broken shale. In it are formed deposits and strata of carhonate ore, hut no sulphnrets. The carhonate ore is fine for smelting, and is shipped to San Francisco for reduction. The last four shipments gave an average assay of $237 per ton. The hlack ore is free milling ore snd is divided into two classes, the first the mill at this place is now crushing, and assays an average of $90 per ton, of which the mill saves 60 per cent., producing bullion 985 fine. The second-class is reserved for future reduction and gives hy assay over $60 per ton. There is now on the dnmp pile over 4,000 tons of second-class ore, and in the tnunels and drifts over 1,000 tons of first-class ore is ready for milling as soon as brought to the surface.

Agricultural Statistics.

The latest issne of the monthly report of the Department of Agriculture at Washington, contains a detailed description of the exhibition which the Department is making in the government building at the Centennial. It appears that a nnmher of large charts have been prepared to show, hy scales and diagrams, the production of the different agricultural staples in the several States. Some of these charts are printed in redneed size in the report and it will he interesting to review them and state the position occnpied hy our State in the showing.

It is shown, hy figuring from total prodnction and amount exported, that the smount of wheat consumed in this country is an average of five hnshels per year for each individual. California produces an average of 29¾ hnshels per capita according to our population. Minnesota produces 42 9-10 hushels per capita. Minnesota is the only State which surpasses California in this respect. Oregon, 25¾; Iowa, 24⅝; Wisconsin, 24¼. All the other States are under 17 hnshels. The New England States do not average a hushel a head and Rhode Island, the least of all in wheat, only 3-1,000 of a bushel to a man.

Another chart shows the proportion of wheat sown hroadcast and in drills. California drills 2 per cent. of her seed; Oregon 19 per cent.

A separate diagram shows the average yield per acre in the several States. California heads the whole list and is credited with a yield of 38.2 per acre, as an average of the crops hetween 1866 and 1875. Minnesota is in the second class and scores 32¼ hushels, Oregon is placed at 29.9.

The wages of farm lahorers, monthly rate without board, from 1866 to 1875, are given for all the States. This shows the fluctuation in the price of farm lahor during this period of 10 years. There is shown to have been a general decline in most States. California is marked at $45.71 in 1866 and $44.50 in 1875. These figures head the list, Oregon heing the next, at $38.25. per month.

A NEW WHEAT WORM.—We learn from the proceedings of the St. Louis Academy of Science that Prof. Riley exhibited specimens of a worm that was just at this time devastating the wheat fields of parts of Kansas, and particularly of Dickinson county. It does not eat the hlades, but attacks the heads. Specimens had been sent to him last week hy Mr. John W. Robson, of Cheever, hut in transit they had all eaten out and escaped from the hox in which they were enclosed. On the way, however, they had moulted, and from the heads alone Prof. Riley had determined the species to he the *Leucania albilinea*, though the insect had never hefore been reported as injurious from the West. Other specimens, just from Prof. F. H. Snow, of the State Univeraity at Lawrence, and from Mr. John Davis, editor of the *Tribune*, at Junction City, proved the correctness of the determination. The species is generically allied to the common army worm, and may be popularly called the wheat-head caterpillar. As it had never till lately attracted nnusual attention, too little was yet known of its habits to warrant any suggestion as to the best mode of destroying it.

The Mining Outlook.

Amid the general depressiou of business in most parts of tbe Union, it is refreshing to find in the precious metal mining industry a very different state of affairs. The far West counts examinstion at present and desires nothiag better than that its claim as a profitable field for iavestment be closely scrutinized. And as success in any one line of trade is bound to ia-fuse life and more or less vigor in all others, the present remarkable prosperity of the Pacifio coast mineral interests may well be regarded as an encouragement to despondent business men of the Atlantic and valley States.

The harvest of the miner is a perpetual one, depending neither on fsir weather nor plentiful storms. Let as glance across the 1,200 miles of mountains lying between Denver and the Pacific, and see what is being done. The inspection will have many elements of interest aside from the array of figures which express the outflow of metal from the bowels of the earth. The wiater has been a long and tedioas one, and though now quite at an end, but a small area of ground is yet fully nuder placer work, not one-fifth of what will be iu the next 30 days. This brunch of our industry produces annually about one-tenth of the annual precious metal yield, or between seven and eight millions, and in an examinution of the oondition of the industry at the present time of the year much of this important item must he disregarded. But what is left makes an exceedingly respectable showing.

Nevada, the silver State, is pouring ont daily $125,000 in silver, $75,000 in gold, $8,000 in lead, and $2 000 in other minersls, making a yield of $210,000 daily, or $63,000,000 per nonum.

California is producing dsily about $40,000 in gold, $10 000 in silver, $8,000 in quicksilver, $5,000 in lead and copper, $7,000 in coal, and fully $5,000 in iron, untimony, zinc, und other minerals. Its total yield is therefore $75,000 oorre ponding to an unnual output from its mines of $23,500,000.

Colorado is prodncing $15,000 in silver every 24 hours, $10,000 in gold, and $1,000 in other minerals, or $26,000 daily, equal to $7,800,000 yearly.

Utah is credited with a daily outpnt of $12,-000 in silver, $9,000 in lead, $2,000 in other minerals; $23,000 per day, or $6,900,000 per year.

Idaho, Montana, Oregon, Arizona, and New Mexico together are turning out each dsy $20,-000 in gold, $17,000 in silver, and $1,500 in bsee metal, giving a totsl of $38,500 each day, or $11,550,000 annually.

Footing these items it appears that from sunrise to sunrise the miaeral regions of tbe western Uoited Ststes throw into tbe markets of the world not less than $334 000 in pure bullion, and $48,500 worth of other metals and minerals. Each hour of the 24 is the parent of $15,521 worth of metal, and each minute of the hour the producer of permsnent metallic value to the extent of abont $260. With nesrly every tick of the Centennial clock in Philsdelphis, a half-eagle rolls out of the mines and takes its place in the world's treasury, the contribution of America to the world's supply of oirculating medium.

It is only by examining closely into the details of affairs that we arrive at a full comprehension of their signifioance. The precious metal mining interests of the United States are to-day a tremendous fact. The production of $111,000,000 of metal each year from a region, three-quarters of which was a howling wilderness 15 years ago, is something to be prond of and to wonder at, and an argument in support of the profitableness of the indnstry that is difficult to be overthrown. Assuming, for the sake of quietiag those habitual growlers who sre continually asserting that profitable gold and silver mining is a delusion, that a billion of dollars has been invested hy the world in openiog and developing the West (a figure nearly twice the actual facts) the investment is now returning an annual intereet of over 10 per cent., and hetore another qnarter of a century is passed will be yielding from 15 to 20 per cent. No amount of outside discouragement or disfavor can stop the work or retard the industry. For the first time in the history of the world, mines practically inexhaustible have fallen into the hands of a race whose energy and intelligence are as profound. When the next century drives the present back into the ages, as the *Review* prepsres its tabular statements of the yield of American mines for 1901, its editor will langh that the record for 1876 was considered so enormous, and gaze with pitying contempt on the wretched $100,000,000 wbich we think so much of to-day.—*Mining Review.*

Peculiar Case of Contraction.—The London *Engineer* states that a few days ago a fly-wheel three tons weight, nine feet in diameter, cast in one piece, having worked for yesrs as part of a steam-engine, was laid horizontally on two balks of timber in the yard of the West Hartlepool cement works, Eng.; the wheel was left perfect at night, and was found next morning tractured in several places, no person having tonched it. The day previous the snn's rays had heated the rim considerably, and the night being cold, the arms having retained but little heat, contrscted too rapidly, snapping from the boss and rim of the wheel.

Useful Information.

Bread Made from Whole Wheat.

When told that it is quite unnecessary to convert wheat into flour before making bread, one is inclined to express some sstonishment; hat seeing certain colors are now mixed, and that on a large scale, without any previous grinding, and without any rubbing at all, thus sweeping awsy with the greatest expenses that attended the trade, we may not refuse to listen to a plan for doing away with the use of millstones, holting cloths, and all the paraphernalia of the flour manufactnrer.

The new system of bread making is the invention, we believe, of a Frenchman named Sezille. Let us state, by way of preface, that according to some scientific men, the total amount of indigestible matter, or bran in wheat, is not more than from four to five per cent. of the whole; by the present method of flour-grinding and bread-making, scarcely 80 per cent. of the alimentary part of the wheat is made available.

Now for the method itself, which is divided into three successive operations:

First.—The wheat is placed in a mash-tub, or other vessel, with more than sufficient water to cover it, and well stirred with a peel for some minutes; by this operation all the overlight and damaged grains, as well as dust and other impurities, will rise to the surface, be dissolved, or held in suspension; at the end of half an hour the water is drawn off, and the wheat having been allowed to drsin, is afterward placed in a cylinder of plate-iron, pierced or worked so as to have the effect of a rasp when made to revolve. With the aid of this cylinder, from two to three per cent. of the outer pellicle, which is the coarser, is easily removed; as to the second skin, and that in the crease of the grain, it only amounts to about two per cent., and might all be left in without injury to the nutritive quality of the bread.

Second.—The grain is now placed in a vessel filled with water, at a temperature of about seventy-five degrees Fahrenheit, in the proportion of about two parts by weight of water to one part of wheat, so that there shall be a certain qnantity of water above the grain; to this water is to be previously added one part of half-dry yeast and five or six ounces of glucose to 200 parts of water. The ferment in the water acts gradually upon the wheat, and after immersion for 20 or 24 hours, according to the nature of the grain and the temperature, the wheat will have absorbed from 50 to 70 per cent. of water, and be ready for panification. The water will now have become of a reddish color, having extracted an amount of the coloring matter from the remaining bran, and is allowed to rnn off; thus another step has been made towards the bleaching of the dough.

Third.—After the wheat has been again drained it is made to pass through one or more pairs of rollers, and, being of the consistency of cheese, it is easily reduced to a paste; by this operation the bran of the second skin has become excessively finely divided, and equally mixed throughout the whole mass. This being done, and the dough placed in a trough, the proper amount of salt to give flavor to the bread is dissolved in water and poured over the dough, and, should the wheat not have absorbed more than fifty per cent. of water, fifteen to twenty per cent. more is now to be added, and the whole is well mixed by being turned over two or three times by hand. The dough is now treated in the ordinary way, rolled and made up into lumps, and left to ferment until the right moment for putting it in the oven.

There is certainly nothing unreasonable in this process; the machinery is of the simplest kind, and the processes such as any baker could carry ont without difficulty. It well deserves a trial, and, although the wish has ungrateful sound, we heartily wish that M. Sezille may have found the method of dispensing with the ase of mills, millstones, bolting-machines, and flour-sacks, and even with the jolly miller and his men.—*Good Health.*

Rough Determination of Weight of Beam Iron.—For rough determinations of the weight of bars or beams of nniform make, where a balance is not at hand, it will answer to measure off the whole of the remainder of the beam and divide this remainder into two equal parts. At the line of their division place the bar upon a support having a full edge. If the bar is symmetrical in form this part ought to be in equilibrium; if, therefore, we place at the extremity a weight which balances the measured yard, we get the weight of the bar. This method of approximative weighing is in use in Belgium, and gives results, it is said, accurate up to a hundredth of the total weight.—*English paper.*

Or-Moulu.—The or-moulu of the brass founder, popularly known as an imitation of red gold, is extensively used by the French workmen in metals. It is generally found in combination with grate and stove work, It is composed of a greater portion of copper and less zinc than ordinary brass, is cleaned readily by means of acid, and is burnished with facility. To give this material the rich appearance, it is not unfrequently brightened up after dipping by means of a scratch brush, the action of which helps to produce a very brilliant gold-like surface. It is protected from tarnish by the application of lacquer.

Bats and Insects.

We make the following extract from a recent number of the London *Farmer:* In the winter of 1875-76, a large number of dead, and, for the most part, hollow trees in the Thier-garten of Berlin, were felled and cut up for firewood. As a consequence of this measure, many thousands of bats, hybernating in these natural retreats, and awaiting the return of spring to renew their energetic campaign against insect vermin, were necessarily destroyed. It is needless to point out here the great utility of these harmless little creatures; any one possessed of the slightest smattering of natural history must be well acquainted with the fact. The question to be considered is how such a needless destruction of useful animal life may be best avoided. Numerous observations have fully shown that bats in a state of hybernation can endure any degree of cold without injury; but that if once disturbed while in this state they are extremely susceptible to change of temperature, and but rarely survive the disturbing intrusion on their sleep. Baron Nolde writes to a German contemporary, suggesting that such trees as form the resting place of bats should be felled only in the warm months of the year, while their inhabitants are in a state of activity, and able to seek fresh shelter for themselves. The only objection in this place is, that labor is more easily and cheaply procured in the winter than in the summer months. But granting this, it by no means allows that by felling such trees in winter is in the long run the cheaper plan. The importance of the bat in the economy of nature has not been properly recognized. He cites the case of a forest belonging to the crown in illustration of this point. Well grown oak trees being required for naval purposes, a notice was issued that none should be felled until the receipt of special orders. Long after the trees had arrived at maturity, the notice remained unrevoked, and they were suffered to run on to a state of decay. This being reported to the higher authorities, orders came to cut down the trees for firewood. The work was undertaken in the depth of winter; thousands upon thousands of hybernating bats died from disturbance and exposure, and the ultimate result was the total destruction of the whole forest, for in the second year after their extermination the damage done by caterpillars—which up to this time had never been specially remarkable—attained such an enormous development as to render the felling of the whole plantation the only practicable course to be pursued.

Carbolic Acid Paper.—According to the *Engineer*, the carbolic paper which is now used in such quantities for packing fresh meats, etc., for the purpose of preserving them against deterioration by atmospheric or other influences, is made by melting five parts of stearine by gentle heat, and then stirring in thoroughly two parts of carbolic acid, after which five parts of paraffine in a melted form are added. The mass thus prepared is then to be well stirred together, until it cools, after which it is applied with a brush to the paper.

Horse Meat.—The consumption of horse-flesh seems to be steadily increasing in Paris, the official report being that during the first quarter of 1876, the horse butchers of Paris have furnished 2,370 horses, asses, and mules for public food, yielding 429,300 kilogrammes of net meat, or considerably more than in the same quarter of last year.

Good Health.

Restoring Persons from Drowning.

The following directions are circulated by the Humane Society of the commonwealth of Massachusetts, 1875:

1. Lose no time. Carry ont these directions on the spot.
2. Remove the froth and mnous from the month and nostrils.
3. Hold the body, for a few seconds only, with the head hanging down, so that the water may run out of the lungs and windpipe.
4. Loosen all tight articles of clothing about the neck and chest.
5. See that the tongue is pulled forward if it falls back into the throat. By taking hold of it with a handkerchief it will not slip.
6. If the breathing has ceased, or nearly so, it must be stimulated by pressure of the chest with the hands, in imitation of the natural breathing; forcibly expelling the air from the lungs, and allowing it to re-enter and expand them by the elasticity of the ribs. Remember that this is the most important step of all.

To do it readily, lay the person on his back, with a cushion pillow, or some firm substance under the shoulders; then press with the flat of the hands over the lower part of the breast bone and the upper part of the abdomen, keeping up a regular repetition and relaxation of pressure twenty or thirty times a minute. A pressure of thirty pounds may be applied with safety to a grown person.

7. Rub the limbs with the hand, or with dry cloths, constantly, to aid the circulation and keep the body warm.
8. As soon as the person can swallow, give a tablespoonful of spirits in hot water, or some warm tea or coffee.
9. Work deliberately. Do not give up too quickly. Success has rewarded the efforts of hours.

How to Treat Sun Stroke.

The unusual visitation of sun stroke in this State during the last three weeks calls attention to a subject which Californians have had very little cause to consider. Although the occasion for remedies and preventatives has probably passed for this time we give them in order that our readers may have them at hand for any future emergency. The sanitary committee of the New York board of health in speaking on this subject says:

"Sunstroke is caused by excessive heat, and especially if the weather is 'muggy.' It is more apt to occur on the second, third, or fourth day of a heated term than on the first. Loss of sleep, worry, excitement, close sleeping rooms, debility, and abuse of stimulants predispose. It is much more apt to attack those working in the sun, and especially between the hours of 11 o'clock in the morning and four o'clock in the afternoon. On hot days wear thin clothing. Have as cool sleeping rooms as possible. Avoid loss of sleep and all unnecessary fatigue. If working in-doors and where there is artificial heat, see that the room is well ventilated.

"If working in the sun wear a light hat (not black, as it absorbs heat) and put inside of it on the head a wet cloth or a large green leaf; frequently lift the hat from the head and see that the cloth is wet. Do not check perspiration, but drink what water you need to keep it up, as perspiration prevents the body from being overheated. Have wherever possible an additional shade, as a thin umbrella, when walking, a canvass or board cover when working in the sun. When much fatigued do not go to work, or be excused from work, especially after 11 o'clock in the morning on very hot days, especially if the work is in the sun. If a feeling of fatigue, dizziness, headache or exhaustion occurs cease work immediately, lie down in a shady or cool place, apply cold cloths to and pour cold water over head and neck. If any one is overcome by the heat, give the person cool drinks of water or cold black tea or coffee, if able to swallow. If the skin is hot and dry, sponge with or pour cold water over the body and limbs, and apply to the head pounded ice wrapped in a towel or cloth. If there is no ice at hand keep a cold cloth on the head, and pour cold water on it as well as on the body.

Do Not Give Way to Fear.—The following from the London *Times* is a fresh illustration of the well known fact, that fear and imagination are sometimes fatal poisons: "On Wednesday, Mr. Langham held an inquest on the body of Mr. George Gillian, who died from fright under the belief that he had taken poison. It appeared that the deceased complained of illness, and his wife by mistake gave him a draught out of a lotion bottle marked 'poison.' The bottle had not been used for some years. The mistake was immediately discovered, and the deceased exclaimed, 'Oh I am poisoned. I shall die.' Medical assistance was obtained, but the deceased died the same afternoon. Dr. Waters said that the bottle originally contained prussic acid, which, however, had evaporated. The body of the deceased did not contain the slightest traces of poison. Death arose from disease of the heart. In his opinion deceased was under the belief that he had taken poison, and the fright caused a sudden failure of the action of the heart. The jury returned a verdict accordingly."

Fruit as Medicine.—Many years ago a chronic cough induced us to look into medical books for the best expectorants. Dr. Good stated that ripe raspberries were one of the best remedies of the kind. As it was then approaching mid-summer, we obtained a daily supply for some weeks. We found them quite an agreeable medicine to take. They cured the cough. Again, at a late meeting of the Western New York farmers' club, Wm. H. Pillow, of Rochester, said he had been in the small fruit business several years, and he believed that strawberries had saved his life. One spring, after severe sickness, he had no appetite till strawberries came, when he almost lived on them, and improved rapidly. Land owners, plant strawberries and raspberries. —*Country Gentleman.*

How Typhoid Fever May be Spread.—Dr. Frankland, in a recent address to the Fellows of the Chemical Society, on the Organic Impurities of Drinking-water, adduced, as a striking instance of the persistency of the typhoid poison when diffused in water, the outbreak of a violent epidemic of typhoid fever in a Swiss village through the use of spring water, which, after contamination with the poison, had filtered through nearly a mile of porous earth, but had nevertheless lost none of its virulent properties. The occurrence in question is one of the most remarkable, if not the most remarkable, on record.

A Grotto of Health.—At Monsummano, in the province of Lucca, high up in the picturesque Apennines, there is a cavern famed far and wide for its beneficent effects on chronic rheumatic sufferers. The invalid breathes the temperate air of the cave, bathes in the medicated waters that drip from its walls, and bids farewell to his sufferings. Such, at least, was the experience of Herr Hugo Knoblauch, a respectable German traveler, who has written a book on the grotto and its effects, well spoken of by our Prussian cotemporaries.—*Medical and Surgical Reporter.*

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 mos.	12 mos.
Per line..... .25	.80	$2.00	$5.00
Half inch (1 square)...$1.00	3.00	7.50	24.00
One inch..... 1.50	4.00	12.00	40.00

Four weeks are ratsd a month.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. C. orders at our risk

THE ORIGINAL ARTICLES in this paper are mostly se in solid type, giving in our columns one-third mor reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:
Saturday Morning, July 22, 1876

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Fire Proof Buildings, 57-68. The San Francisco Foundries; The Highly Important and Practical Value of the Mechanics' Institute Fair; Comstock Papers, 64-65. Improved Amalgamating Pan; Taking the Gravel Banks by Storm; Interesting to Miners; Placer County Mines, 65. Alpine County—Its Mines and Resources, Past, Present and Future; Patents and Inventions; Notices of Recent Patents, 68.

ILLUSTRATIONS.—Fire Proof Brick, 57. Cumming's Amalgamator; Hydraulic Nozzle Attachment, 65.

CORRESPONDENCE.—Overland Chat, 58.

MECHANICAL PROGRESS.—New System of Grinding in Germany; New Electric Motor; An Ingenious Contrivance; English Quarry Working; Counterfeit Coins; Metallic Pyrometer; A Hundred-ton Gun, 59.

SCIENTIFIC PROGRESS.—The "Man-root" of Colorado; Salt in the Sea; Constitution of the Sun; Phenomenal Effect of Rock Boring; A Shower of Sulphur; Limit of Strain in Iron; Brazilian Gems; A New Microscopical Drawing Apparatus; Value in the Violet; Eucalyptus Leaves and Oil; Ammonia in Rain; Metrical System in Sweden, 59.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 60.

MINING SUMMARY from various counties in California, Nevada, Oregon and Montana, 61.

USEFUL INFORMATION.—Bread Made from Whole Wheat; Rough Determination of Weight of Beam Iron; Ce-Monia; Bats and Insects; Carbolic Acid Paper; Horse Meat, 63.

GOOD HEALTH.—Restoring Persons from Drowning; How to Treat Sun Stroke; Do not Give Way to Fear; Fruit as Medicine; How Typhoid Fever May be Spread; A Grotto of Health, 63.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 68 and other pages.

MISCELLANEOUS ARTICLES.—The Defiance Strike; A Gold Varnish; Coal Resources of Contra Costa County; The Fan Method of Ventilating Mines; The Central City Tunnel, 58. The Centennial Ode (Poetry); Oregon's Representative Mine; Arizona Mines; Agricultural Statistics; A New Wheat Worm, 62. The Mining Outlook; Peculiar Case of Contraction, 63.

NEW ADVERTISEMENTS.

Miners Wanted, Edmund C. Burr, Mariposa County, Cal.; Patent For Sale, Geo. G. Buckland, Calaveras County, Cal.; Cherokee Flat Blue Gravel Co.—Sale; Kearsarge Con Quicksilver M. Co.—Assessment; South Comstock G & S M Co.—Meeting; Tintic M. & M. Co.—Meeting.

A STRIKE IN EL DORADO COUNTY.—In a recent letter of our correspondent from El Dorado county, was a report of the Volcanoville mining company, situated in Volcanoville. Since our correspondent examined the mine, which was being worked by a hydraulic nozzle, the owners write us that they have struck some of the richest rock they ever saw in California. They have found a well defined ledge from three to five feet wide. They are down on it 50 feet, with the ledge exposed for 100 feet in length. Gold can be plainly seen all through the vein from one side to the other. They have beaten out some of the rock with a hand mortar and estimated that it will mill about $400 per ton. They consider that they have one of the best prospects in that part of the county. They are taking out pure specimen work every day showing the gold in large pieces. A mill is to be erected immediately. There are only three shares in the mine, owned by three miners, J. B. Watkin and the Graves Brothers.

THE SILVER QUESTION.—We give in another column the full text of the "silver bill" as passed by Congress. The question is becoming a most important one for us on this coast, as it very seriously affects the mining interests. The steady and persistent decline in silver has already had the effect of partially closing down several mines, and others are mentioned as about to close down, among them the Richmond of Eureka. The outlook for the silver mines is at present rather gloomy.

GEMS AND PRECIOUS STONES.—Mr. Hauks' continued article on this subject is unavoidably deferred this week, but a double article will appear in our next.

The San Francisco Foundries

The principal manufacturing establishments of San Francisco are the iron foundries which are of a character that would be creditable to much larger and older cities. For many years the whole coast was almost entirely dependent on the foundries of San Francisco for necessary iron work of all kinds, and even now, although imported machinery is more plentiful, the majority of the work is performed by our machanics. Of course under these circumstances every variety of work has to be performed, from monster mining machinery to the simplest castings, and our foundries are often put to much more severe tests than the much larger ones in older communities. The principal ones have now machine tools capable of doing any class or size of work, and doing it well, so that they can turn out as good jobs as any foundries in the country.

Of course on this coast the principal large work is mining machinery, and of late years the city foundries have built more massive and magnificent machinery of this kind than ever before made. As the mines in the great Comstock lode have increased in depth, the difficulties of hoisting and pumping have materially increased, and what was considered large machinery ten years ago is now looked upon as insignificant. Sixty-stamp mills are now nothing unusual, and more iron is put into one pumping or hoisting outfit than was used in half a dozen ten years ago.

There are in San Francisco 17 foundries, machine shops, boiler manufactories, etc. Some of these are of course on a small scale, while several will compare favorably with much older institutions in the Eastern States. These different shops employ altogether from 2,500 to 3,500 men. They pay annually for wages upwards of $1,000,000. The wages of mechanics are fully 33⅓ per cent. higher here than elsewhere, so the foundries are seldom short of men. Skilled labor receives from $3 to $4 per day. A few receive more, but that may be taken as an average.

Although the foundry business has been generally profitable here, it has had many serious drawbacks to contend with, prominent among which has always been the lack of certain descriptions of material. Pig iron and iron have long stood in the way of the manufacturers, and do so still. The price of coal will range from $8 50 to $20 per ton, according to its class. Pig iron is worth about three times as much as in England or Pennsylvania, and there was upwards of 17,000 tons of it used here last year. Moreover, everything that is ordered is wanted in the greatest hurry possible. The mining companies in particular never make up their minds what they want until they absolutely need it, and then it must be turned out immediately. Plenty of jobs of this kind have been undertaken and furnished by our local works in a space of time which would look preposterous in older communities. Within the past few months the larger foundries have been crowded with heavy orders of this kind, which they were required to fill within a limited space of time.

The foundries have, however, been fully up to the requirements. They have procured the best of tools capable of doing the largest work and the mechanics are as good as they make them. The superintendents of the different foundries all have an intimate knowledge of mining machinery as well as a varied experience in general foundry business. Those in the three principal works have under their charge continually from 300 to 500 men, and have lately constructed some of the largest machinery ever made. The work has to be well done, as so much depends on it and any slight error in construction might endanger the lives of many. As no complaints on this score have ever been made we may conclude that the work is generally as good as can be done. It is not generally understood, but is nevertheless a fact, that people on this coast expect more out of machinery than they do anywhere else. An engine is generally made to do twice as much work as it is expected to do by other people, and the machinery must be made strong enough to stand these requirements. The Eastern made engines do not as a usual thing come up to the California standard.

As Californians we should be proud of the position which our foundry interests have taken among those of the land, and should also foster them as far as lies in our powers. Our mechanics do work here at home which few people fully appreciate. In mining machinery we can, of course, beat the world and in general work we are not at all behind. Some of the marine machinery turned out within the past few years by our local works would do great credit to any foundry, and in strength, durability and finish cannot be surpassed. Many would be surprised to see what is being done in that part of the town where the foundries are located, should they take a stroll in that direction. Iron work of any character, large or small, can be procured at short notice and turned out in first class style. At present the shops are busy, although the best of the season has past and some of the larger works have just completed a number of heavy jobs for the Comstock mines,

The Highly Important and Practical Value of the Mechanics' Institute Fair.

The time is fast approaching for the opening of the Mechanics' Institute Fair in this city. On the 8th of August the great pavilion will again throw wide its doors to the public; and the public, educated and interested by its former experience within the walls, will press forward again to read the industrial progress of another year. The prospect is that they will not come in vain, and that this year's fair will surpass all that have gone before in all those things which constitute success in an industrial exhibition.

The applications which have been already made for space exceed the former limits. The popular spirit and the popular interest in the efforts of the managers of the Institute give full assurance that the people are with them, and their work will result in the grandest display of industrial achievements ever made in this city. As this is the case there are several suggestions which we regard pertinent to this occasion.

Honorable and worthy industry thrives by popular approval. To secure approval attention must be arrested and examination courted. Industrial lights do not burn well under bushels; they must be put forward into the free air of popular contemplation. Every producer, every manufacturer, every man who gives form to a worthy work of hand or brain, every man who has succeeded in wrestling things of value from the natural resources of the coast—all these classes of workers owe it to themselves to give their work the advantage of a popular display. They owe it to their own success and to a public to whom their work may be of benefit. In these busy days the people have not time to search long for excellence. They must look, think and act in a moment. They have come to look upon excellence as a thing which is sure to rise where all can see it. In these days of quick thought and wide information, to be unknown is almost to be worthless.

As this is the disposition of the age, wise men have learned to profit by it. The result is that the triumphs of industry, instead of hiding away in by-places, as they did in former years, come out now into the broad daylight of public scrutiny, trial and admiration.

Fostered by this praise and patronage of the people, the industrial spirit has taken to itself new life and strength. Catching new thought from the clash of competitive display, ingenuity has been sharpened, industry has been doubled, and success has been wonderfully promoted. The history of industrial advancement is inseparably connected with the history of industrial exhibitions.

The thought of these truths lead the mind to the opening of the Mechanics' Fair, to which we have alluded. It is impossible to measure the good work which has been done for the industries of this coast by the Mechanics' Institute. Limits cannot be placed to it because the spirit of progress and advancement, which it has implanted and fostered, is still expanding. The full influence of the Institute cannot be measured so long as there is a hammer left to strike, or an anvil to sound the ring of industry on this coast. The Institute works for all our future, and its work will not be done until the honorable labor and enterprise of this coast shall have done their perfect work, and our full growth and greatness shall be achieved. In the hurry of the present we are too prone to forget the future of our labors. If we judge the Mechanics' Institute by the good it has already done and the industrial growth which has already been gained, in no small part by its labors, we have some basis on which to rest an estimate of its value as a factor in our growth and progress, and foresee its future position among the institutions of the coast.

The Mechanics' Institute is a popular institution. It purpose in the ripeness of time in answer to a demand of our industries. It was wisely planned by men whose heart was in their work and whose tireless energy shrank from no effort.

It has ever grown and prospered by the inherent right which there is in it and by the self sacrificing devotion of those in whose hands its management has been entrusted. It is not necessary to recite its history. The facts are generally known. It is not necessary to mention its patrons and promoters. Their names are already written in the public mind in connection with a score of honorable institutions and enterprises of which we are proud.

We have, however, a direct word to all readers, to all patrons of industry and to all workers in our industrial arts. The Fair of the Institute gives opportunity to exhibit excellence. No better opportunity can be devised. The popular eye will be turned toward your labors. The popular mind will be in a frame to study, to compare, to patronize. You may catch a man's eye as he passes along the street, you may gain his ear by calling upon him at his place of business but at such times and places his mind is occupied and the impression you make is generally slight. At an industrial exhibition his disposition is different. He comes for the express purpose of hearing, seeing and judging for himself. The lesson is plain. Every manufacturer and tradesman is neglectful of his own interests if he fails to avail himself of the privileges of the Institute and place his best articles on exhibition.

To the inventor, the man who has made a new and valuable device for improved an old one, the opportunity of exhibition is invaluable. His success depends directly upon the extent to which he secures the popular eye. He might be almost as well out of existence as out of the thought of men. Let our inventors then come forward without exception and serve their own interests and at the same time display the inventive spirit of the coast so that all can see and admire it.

To the mechanic, the man who swings the hammer or holds the calipers, a mechanics' fair is of great importance. The mechanic's thought, like the scholar's, needs new material; it profits by suggestion and grows by the original adaptation of hints gained, from study and observation. Every mechanic should elaborate his best mechanical idea, whether it be in original work or in the excellence of workmanship on some frequent task, and place his masterpiece where all can see it. The demand of the day is for the most skillful workmen. Common laborers are abundant. Let it be seen that your work is not common. Do something above the ordinary run of work and put the result where all can see it at the Mechanics' Fair. It will do you good. It will show your ability, and depend upon it, there are many interested eyes seeking for the best skill and will bid high for it.

The coming Fair commends itself to the people of this State in every way. We have only pointed out, in an imperfect manner, a few directions in which its usefulness lies. As we have said before, it is an institution of the people. Its officers are but discharging a trust for the whole people. They deserve the fullest patronage and support. They should receive the earnest co-operation of every friend of industry on this coast. There are indications that they are receiving this, for the prospect for the coming exhibition is very bright. But there are some useful things, we doubt not, which are not yet entered for the display, and some enterprising citizens who have neglected to take the part which it will be for their own and the public interest that they should take. To such as these, if such there be, we would make a direct appeal to come forward and show their appreciation of the labors of the Institute, by contributing whatever excellent thing they have, to secure for this Centennial exhibition of this western shore a fullness and excellence which will be always memorable.

Comstock Papers.

NO. 1.

Discovery and Early History of the Great Washoe Lode—Singular Misapprehensions in Regard to the Facts.

That the Comstock lode, in the item of active production, surpasses every other gold and silver bearing ore channel of which we have any knowledge, admits of no question. Other veins may have been discovered and worked in both South America and Mexico, carrying ores of higher grade, and from which larger aggregate sums may in the course of centuries have been taken, but from none of them has the annual product of bullion been half or perhaps one-quarter so great as from this. These slow going countries, with their crude machinery and their man and mule power, required 10 years to accomplish what we, with the aid of steam and other modern inventions, accomplish in one. Throughout all the mining regions of Spanish America it was formerly, as it is almost everywhere still the custom, to bring the ore to the surface on the backs of men, to raise the water in buckets and drive the arastras and nearly all other machinery by mule power, as many as 1,400 of these animals having been kept for this purpose and for treading the patios, in the district of Guanajuato alone. The machinery employed on some half-dozen claims on the Comstock lode would be more than sufficient to perform the service exacted from these 1,400 overworked and underfed brutes, supplemented by whole armies of equally hard-faring men. It is this capacity to

Perform Much in a Short Time

That gives to the mother lode of Washoe its superior importance as compared with the most renowned *Veta Madre* of these older and historically famous mining countries. And yet the out-turn of these latter has for more than 300 years been remarked upon by scientists and political economists as of vital consequence to the commerce and industries of the world. The chroniclers of the past notice it as a feat worthy of special comment that Mexico and South America combined should have been able to turn out gold and silver at the rate of $20,000,000 per year. Since the conquest of Mexico by the Spaniards, that country has produced an annual average of only about $8,000,000, this being the rate at which Peru and Bolivia, the great bullion producing countries of South America, have turned out the precious metals in the meantime.

The State of Nevada has yielded to date over $300,000,000, being at the rate of $20,000,000 per year since the business of mining was here first actively engaged in. Of this total about two-thirds came from the several mines situate on the Comstock range. The most prolific ledge in Mexico yielded during a period of 284 years an average of not quite $2,500,000 per annum, while the richest in South America, that of Cerro del Potosi, in Bolivia, yielded less than $5,000,000 per annum during the 250 years it was worked.

From two claims on the Cometock, the Crown

Point and the Belcher, covering jointly a lineal section of 1,480 feet of the ledge, there were extracted, in the space of three years, $50,000,000, of which one-half was dishnrsed in dividends to the shareholders. Within the past two years there have been taken from the Consolidated Virginia mine alone about $35,000,000, of which over $20,000,000 were net profits. Dnring the year 1873 the dividends declared to shareholders in the varions mines a ong the Comstock amounted to $22,000,000, o rate of clear earnings that has since been maintained.

That the Productive Era

Of an ore channel so veat and marked by features of such permanence will extend into the distant fntnre may well be expected, this being in accordance with geological facts and all previous experience. History teaches that silver mines situated at these high altitudes and oo cnpying great notural chasms never wholly give out. Mexican mines opened by the Axteos still continne to yield well, and there are districts in Spain that were operated before the Christian era, which to this day richly repay the labor bestowed npon them. In many parts of Europe there are silver mines now being worked with profit that were opened from 500 to 1,000 years ago, thongh none of them exhibit the masterly proportions of the great dominating lode of Nevada.

That the facts connected with

The Discovery and Early History

Of a gold and silver hearing vein that has already yielded so largely of the precious metals, and is destined to occopy such a conspicuous place in the annals of mining, should have been so misapprehended, not to say strangely perverted, is a circumstance to be accounted for only on the hypotheses of sheer cerelessness or indifference on the part of those who first nndertook to make public record of this event. According to the generally received version of this affair, the finding of the Comstock lode was due to certain parties who, while excavating a hole to collect water for gold washing, threw up a qnanity of earth mixed with free gold and the decomposed snlphurets of silver, this rich material consistiog of the disintegrated out-crop of the main lode which here came to the surface. This excavatioo was made on the dividing line between the old Mexican and Ophir cloims, being near the southerly eod of the present Ophir grond. Prior to this incident, which occurred in the latter part of May or early in Jone, 1859, James Finney, commonly koown as "Old Virg nny," had located n quartz claim on the line of croppings a little to the west of the Comstock, afterwards known as the Virginia ledge, hut had done no work npon it. This claim, which was recorded on the 22d day of February, 1858, was taken up because the locator considered it to be on the ledge previously occupied end already extensively worked at Gold Hill, a mile and a quarter farther south. These croppings, though quite hold, were not, however, on that ledge at all, or at least not on the main Comstock, which, as has since heeo shown, lies several hundred feet to the east of them.

The Real Site of the First Discovery.

Now, it will not he denied that the ground of Consolidated Imperial company is on and constitutes a section of the Comstock lode, and as this grond was occupied and extensively worked as early as 1857, it follows that the discovery of the lode must anteda.e thet event. More than a year before Finney had taken up his claim on the croppings of the Virginia ledge end more than two years before Peter O'Reilly and Patrick McLaughlin, the gold washers, had dug the excavation mentioned, a nnmber of arastras were being run on the rich ores et Gold Hill, quite a hamlet having already sprung up at that place. That the parties operating here had little idea of the magnitnde or importance of the lode they were working and were wholly ignorent of its extension either to the north or south, must he admitted. But that they were really on the Comstock and were well advised as to its character at that particular point, cannot be questioned. If to ony one, then, the credit of discovering this lode is due, it belongs to these quertz workers at Gold Hill, who had been opening it up and crushing its ores for so long a time before the rich surface deposits were struck upon it farther north at Virginia City. It is not claimed that there was much merit in their being there. They had worked out Gold canyon, which afforded fair placer diggings, and having arrived at its head and found there a heavy reef of rich quertz, went to work upon it, treating it simply as an auriferous ore, never dreaming that it would at greater depths rnn into silver, or thet heavy deposits of that metel existed in the neighborhood.

The Grosch Brothers.

So far as seerching after argentiferous ores wes concerned, the idea does not appear to have entered the heads of any of these pioneer Washoe miners, if we except from the number H. B. end E. A. Grosch, commonly spoken of as the Grosch Brothers, two young men who came over to this region from Placerville, California, in 1852. While they made gold washing their principal business, they seem to heve entertained the idea that there was silver also in the country, and being educated mineralogists, with some knowledge of metallurgy, spent much time in seeking after this class of ores. That they succeeded in finding what they considered silver-bearing lodes is well established, they having carried to California and there exhibited samples of ore carrying a considerable percentage of that metal. By some it hes been claimed that they obtained these samples from the Cometock ledge. But this is obviously a mistake, noless we consider the ore channel that passes through the present Dayton claim as being on the mother lode, for there can be no question but they obtained their best specimens from that neighborhood. On a sort of bench, 200 feet above the American ravine, and on a line with the Dayton croppings, the remains of a shaft sunk by these young men are still to be seen, the fragments of a rude furnace erected near by and nsed hy them in experimenting npon their ores being also visible in 1859. They probably never pushed their researches further north than Gold Hill. Certain it is, if they had ever found any of the rich silver ores of the Comstock proper, or at least such as were first struck at Virginia City, they, being qualified to appreciate their value, would have teken measures to secure the discovery and turn it to practical account. The fact is, they never found any ores of that character; yet to these men more than to ony others is due the merit of having first paid attention to the snbject, and of actually engaging in a search after silver ores on the "Eastern slope;" and it is not improbable that they would, had their lives been spared a little longer, have been instrnmental in making more important discoveries of this metal.

Next to these brothers in the list of those who may with any propriety claim even an indirect agency in bringing about the discovery of the great Washoe *Vela Madre*, stand the early Gold Hill quartz miners, followed by Finney, O'Reilly end McLaughlin, in the order mentioned, Comstock, whose name the lode hears, having had no more to do with that event than the man who is supposed to occnpy the lunar attendant on our planet. The circumstences thot led to this singular and awkward misnomer will he expleined in the next number of the Comstock Papers.

Improved Amalgamating Pan.

We illustrate on this pege an improvement on grinding end amalgamating pans recently pateoted through the MINING AND SCIENTIFIC PRESS Patent Agency, by Charles Commings, of the Union iron works, Virginia, Nevada.

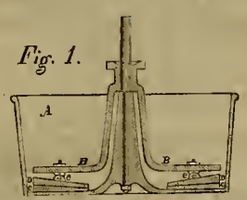

Fig. 1.

Fig. 2.

Cummings' Amalgamator.

The main principle of this invention consists in constructing the shoes and dies with a gradually increasing thickness or metal towards their outer edges, where they are subjected to the greatest amount of weer. This arrangement improves the efficiency and dnrehility of the shoes and dies which are nsed in grinding and amalgamating pans, saving not only in the superior manner of triturating the pulp, but in the length of time that the shoes and dies will run without replacing, as it is always a considerable item of expense to stop the pans to remove worn-out shoes and dies and replace them with new ones.

In the engraving, Fig. 1 is an elevation in section of the pan, and Fig. 2 is a view of one of the shoes. *A* represents the pan and *B* the muller. Owing to the rotary motion which is imparted to the muller, the outer edges of the shoes and dies, where the speed is greatest, always wear away much faster than that portion which is nearer the center, and which consequently moves at a less rate of speed. On this account, therefore, it is impossible to maintain a uniform grinding surface, as the faster motion of the outer extremities wears the metal of the shoe away so much faeter than near the center where the speed is slower, thus requiring more power to do the same work then if the grinding were done at the outer extremity.

To remedy this difficulty Mr. Cummiag constructs the dies *C* and shoes *D* with a gradually increasing thickness of metal towards their outer edges, so as to render them more durable and obviate the necessity of changing them so often. The dies *C* are rigidly secured to the bed of the pan as shown, but instead of fixing the shoes *D* rigidly to the under side of the muller, they are attached by means of a pivot or loose joint as at *e*, so they can adapt themselves to the irregnlerities of the wearing surface, and thus maintain an even and uniform surface at all times, no matter how much they may become worn.

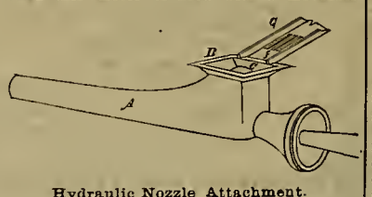
Any suitable pivot or hinge joint can be employed that will let this shoe vibrate or move freely, and the hinge or joiot may extend entirely across the middle of the shoe, or it can be merely a point attachment at their centers. Although shoes and dies of uniform thickness can be used with this method of attechmeut, a great advantage is gained in their durability by making them thicker towerd their outer edges.

Taking the Gravel Banks by Storm.

Rather a curious invention, of recent date, in the line of mining appliances, is one intended to increase the effectiveness of streams of water in hydraulic mining, which is done in a novel manner. It consists in the introduction into the stream of water, either before or after it runs from the nozzle, of stones, gravel, sand, or other bodies which, by their superior density and solidity, will admit the erosive action of the water, and more effectually pulverize the gravel. It is claimed that this will accelerate the operations of disintegration and more effectually release the gold from the large pieces of cement

The device for accomplishing this object is called a "hydranlic motor," an engraving of which is shown herewith. *A*, represents a tube or pipe 10 or 15 feet long. The pipe is mounted directly in front of the hydraulic nozzle so that the stream will enter the rear end of the pipe *A*, and pass through it. Near the rear end of the pipe is a hopper, *B*, upon it, and the hopper is connected with the interior of the pipe by a throat, *C*, so that the stones or gravel can be dumped with the hopper, pass through the throat into the passing stream and be carried by it against the bank. The throat, *C*, gradually widens from the bottom of the hopper toward the front of the pipe, so that the stones, etc., will have room to descend freely and not choke the passage. The stones can be dumped into the hopper by any convenient means; but as a stream of water soon as is nsed in hydraulic mining is capable of carrying a vast amount of foreign substances with it, in order to render the operation complete it should be quite strongly charged with stones or gravel.

The better way, the inventor thinks, is to construct a screen or "grizzly," *G*, on the side of the hopper. A trough or sluice is led from the bank which is being washed, to this grizzly, so that a portion of the stones and gravel which are dislodged by the stream will be caught by the sluice and conveyed into the hopper, thus automatically feeding the stream with missiles. The grizzly seems to draw off the water and sand, or a portion of them, before they enter the hopper. The bottom, *f*, of the grizzly is constructed to operate as a slide, so as to regulate the amount of water and sand to be drawn off. The pipe, *A*, must be larger in diameter than the nozzle from which the stream issues. When this motor is nsed with a moveable



Hydraulic Nozzle Attachment.

nozzle it is attached to the nozzle so they will both move together.

By loeding the stream with missiles as described, it is claimed that the efficiency of the stream is largely increesed. The stones seem to break np the pieces of cement or earth that are detached, thus freeing the gold from the lumps. The missiles nsed are not large enough to impede the flow of water through the sluice, but will keep up an agitation of the materiel in it and help form numerous eddies of comparatively still water which will favor the settling of the heavy particles. This method of "hydraulic bombardment" is the invention of the late Jasper O'Farrell end Dr. Ambrose Blatchley, of this city.

Interesting to Miners.

A correspondent writes as follows: "The issue of the 8th inst. of the MINING AND SCIENTIFIC PRESS has been received. Each number seems to excel the other in valuable information. Your El Dorado correspondence is especially interesting. I only regret my inability to furnish yon items written in a manner worthy of place among the snperior articles which appear in the PRESS!" This is a sample of the letters of encouragement we frequently receive, and we always feel gratified thet our efforts to meke a good paper are appreciated. Mr. Knox, our correspondent who has been writing up the interests of El Dorado and Placer counties, has written some very interesting letters which seem to be appreciated. We hope our friends will aid him all they can in his tour.

We commence in this issue a series of articles on Alpine county mines, which will be found of great interest. We also commence a valuable series of papers, giving a historical account of the great Comstock lode, which no one interested in that locality should fail to read. New subscribers now will be eble to receive the whole series. We have in preparetion a number of other articles of great value to the mining community which will appeer in due time. We intend to continue to improve the PRESS in snch a manner that no mining men can afford to be without it. The articles which are now running in series in the peper are alone worth the price of subscription and others on hand will still more increase its value.

Placer County Mines.

[By our own Correspondent.—No. 3.]

There is a very extensive body of gravel aronnd Iowa Hill; much of it is as excellent in quality as abundant in qnantity, showing in many clsims the true characteristics of whet is known as the blue lead. The want of a sufficient supply of water has been the great drawback. This has been remedied to a great extent. The Iowa Hill canal has been completed the distance of 45 miles; it will he extended 14 miles further. A large reservoir has been built with a present area of 100 acres, and when contemplated embankments are finished will cover a space of 200 more. It supplied last season 300,000 inches of water. With a little more capital to overcome this and some other difficulties, it would become one of the liveliest places in the State. The shipment from this place, including Damascus, during the half year just ended, amounted to $120,000. The Orion claim has 90 acres of pure gravel from 100 to 175 feet in depth, being clear of timber end cement, and is said to prospect well from surface to bedrock.

The North Star

Has yielded up to dete over $500,000. The Enterprise was partially opened last winter, running with a head of 400 inches of water, and paid good wages for the amount of work done. It turned out from $125 to $200 per day.

The Morning Star

Has about 80 feet of as beautiful blue gravel as one could wish to see—the whole bank 150 feet in hight. As it is worked into the hill it will probably reach 500 feet. It is opened with a face 700 feet in length and covers about 60 acres. The flume is four and one-half feet in the clear; grade eight and one-half inches in 12 feet, and 900 feet long; from 1,000 to 1,200 inches of water used under pressure of 500 feet. I noticed here two of Hoskin's letest improved little giants. This claim labors at present under a great disadvantage from a want of sufficient fall. Notwithstending it has done well, yielding on the first run of the season (15 days) about $8,000. Under more favorable conditions in anticipation it ought to yield enormously.

Not far from this comes

The De Kruse Claim,

Of 24 acres, with a similar bank of gravel 120 feet in hight, and about 30 feet of the blue streak that peys exceedingly well. There is a good outlet through Little Indian canyon, which belongs to the olaim. It averages $2,800 per month, requiring the labor of about one-half dozen men. The Irish & Byrne, adjoining, covers 100 acres of similar ground, with ample fall for all time to come. Two out of four hydraulic mines are running at Wisconsin Hill. Messrs. Vaughn and Ingersoll have a bank from 80 to 100 feet high, not having cut through the deep channel of cement to the bedrock. They have taken ont about $75,000 within the past nine years, late runs averaging about $16,000 per month.

Horman & Co. have 100 acres with a good outlet in the heed of N. Y. canyon and bank on the west side of claims of 130 feet. They intend to run a new tunnel from the canyon 300 feet in length to work the channel. The district assessor ought to make it pan out well when he makes them a visit, *verbum sat.* All the public need know is thet they have had a lengthy and profitable run.

Across the ravine

On Prospect Hill

Is the Lebanon company's ground. They have crushed some cement this season with very good results. It averages them in their 10-stamp mill $6 to $7 per ton, occasionally getting a rich seem that paye as high as $100. They have run a tunnel 3,000 feet in length, cutting a good quertz vein, from which fine gold quartz specimens have been taken, valued at from $30 to $60 apiece.

The Belte claim on one side, worked by hydraulic, has the appearance of being very good ground, and on the other side of the Lehenon is the Wesley, a drift claim of 46 acres, that pays $10 per day to the man. As high as $2,000 have been taken out here by the labor of two men in a single month. Mr. C. F. Schwab has 55 acres of excellent hydraulic ground adjoining.

On Independence Hill,

The Barber claim, though not yet fully tested, as the bedrock has not been reached, is said to prospect very well, while the adjoining one of Messrs. Entwistle & Worsley, now thoroughly opened, has paid handsomely, although they had not fully cleaned up.

The Gophir, on the same hill, the property of Mr. E. Metcalf, has a bank of 100 feet. A face of 600 feet had been washed off a distance of 300 feet into the bank, out of which about $25,000 had been taken. K.

THE East Justice mine is located immediately east of the Alta and Woodville mines on the Comstock and but 200 feet from the Alta hoisting works. A number one three-compartment shaft has been commenced and the sinking will be prosecuted vigorously.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 426 California street, Room 1.

Rupture.

Any person suffering with the dangerous and distressing complaint, Rupture, and whose existence is rendered miserable, being obliged to wear the torturous metal trusses year after year without any benefit or relief whatever, can be relieved and cured without inconvenience or restriction in exercise or diet. Consultation and Examination Free. Call or address MAGNETIC ELASTIC TRUSS CO., 609 Sacramento street, (up stairs,) San Francisco.

Machinery.

The Ingersoll Rock-Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and HAS AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

426 California Street

Sole Agents for California,

9 and 11 First Street, - - San Francisco.

THE O'HARRA

CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
1500 lbs of salt at 1½c	22 50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93⅓

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

W. F. & JNO. BARNES,
Manufacturers of
Barnes' Patent Foot Power Machinery, Scroll-Saws, Circular Saws, Lathes, etc.

The only Foot Power Machine without crank or dead centers. $1,500 to $2,000 per year made using these Machines. Send for Illus'd Catalogue
Rockford, Winnebago county, Ill.

DEETKEN'S

ROASTING FURNACE,

For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 6 to 60 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adopted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

G. F. DEETKEN,

Consulting Metallurgist, Grass Valley, Cal,

Furnace can be seen on application for permit, at Grass Valley.

Buffalo Excelsior Pony Planer & Matcher

Hatters,	Jewelers,
Hotels,	Piano Fortes,

Wine Merchants, Etc., Etc.

SODIUM AMALGAM.

I am prepared to furnish Sodium Amalgam for $1.50 per pound. Although the price is low, my reputation is a guarantee of its purity. Sodium being now much cheaper than formerly, the miner and millman should have the advantage of it. The temptation to adulterate the article being so great, consumers are advised to call for my manufacture when ordering from wholesale dealers, with an assurance on my part that the quality will be the best. Zinc is sometimes substituted for sodium, to the great disadvantage of the consumer. The following are the tests for pure Sodium Amalgam: shaken up with water it must be wholly decomposed, the mercury remaining perfectly fluid and the water becoming strongly alkaline.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Our new Mining Engine is built from plans and specifications of several of our MOST SUCCESSFUL MINING ENGINEERS, and the result is the most complete

Double Drum Hoisting Engine

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

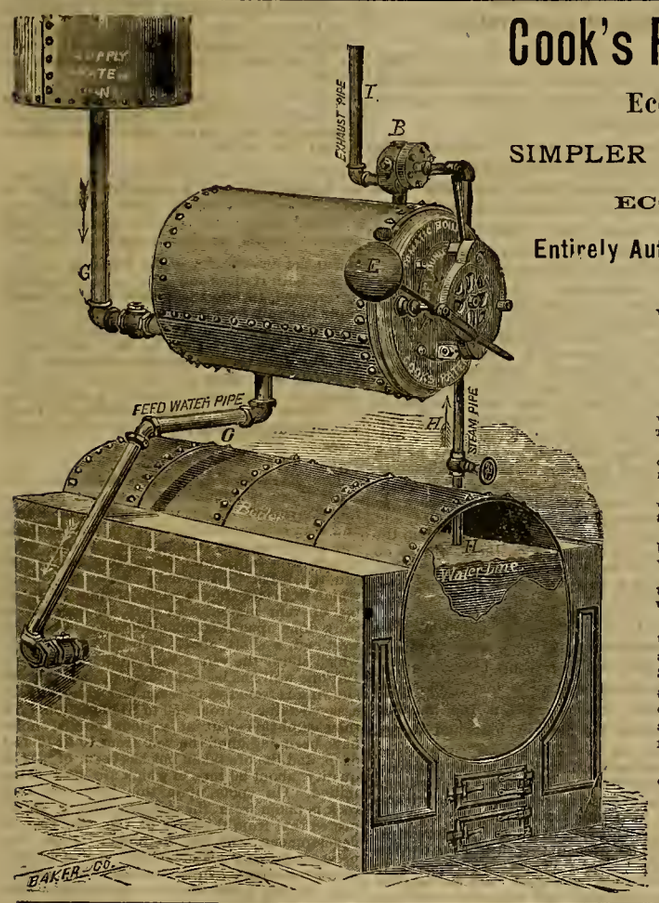
Cook's Patent Automatic Boiler Feeder & Regulator.

Economy in Operation. Absolute Safety from Explosion.

SIMPLER THAN A PUMP, AS IT REQUIRES NO ATTENTION.

ECONOMY IN FUEL.

Entirely Automatic, Reliable & Durable.



Cook's Automatic Boiler Feeders

WERE AWARDED THE HIGHEST PREMIUM OVER ALL MACHINES EXHIBITED AS BOILER FEEDERS AT THE CINCINNATI EXPOSITION AND THE ST. LOUIS FAIR.

The cuts show the operation of the Feeder. It was described in detail in the MINING AND SCIENTIFIC PRESS of May 20, 1876.

This Feeder will discharge from 40 to 200 gallons of water at one movement, where a pump would require hundreds of strokes to do the same work.

The water is kept exactly at the proper line, whether running fast or slow, without attention from the engineer.

Feeders, Heaters and Regulators Combined are made on this principle. Simple and economical.

The control of feeding water to the boiler is taken out of the hands of the engineer and left to unerring natural laws.

These Machines are now introduced on this coast for the first time, although they are extensively used in the Eastern States. They supply the boilers with great regularity, and keep the water at exactly the same level. As a protection against explosion they are simply perfect, leaving nothing to be desired.

ONE OF THESE FEEDERS CAN BE SEEN IN OPERATION AT THE PACIFIC IRON WORKS.

Address,

(Continued from Page 57.)

of worship, public halls, etc., reflect remarkably the voice of the speaker and the notes of music.

Their fire-proof qualities are too evident to be spoken of. However, mention may be made of this fact that, with them, bank vaults are said to be safer than with solid brick or stones, owing to the air which the walls contain. They are invaluable as a substitute for wooden partitions, to which, as just demonstrated, the largest number of devastations by fire may be ascribed.

As regards their strength, it is difficult to compare them with common bricks, as the latter are sometimes thoroughly burnt and hard, but frequently very deficient in these particulars. Still it may be said that they are to solid bricks what hollow iron is to solid iron—that is to say, generally stronger. Their resistance to pressure has been so often tested, officially and otherwise, during the first few years of their introduction in Europe, that nobody there thinks of resorting to new experiments.

In 1853 Mr. Hodge, architect of the Congregational church and school of Battlebridge, in the district of St. James and St. John, Clerkenwell, London, before using Borie's hollow bricks in these buildings, piled 30 tons on four of them until the beams and planks, which supported the weight, began to yield and prevented laying more on. This was left piled up for several weeks, without the least injury to the four bricks, thus showing that a hollow brick will sustain, without danger, a column of the same size and material equal to three times the hight of the pinnacle of St. Paul's in London. Then the official referees, appointed under the Metropolitan Buildings act, to determine whether this kind of bricks was fit to be used in the said constructions, awarded affirmatively. (Vide *Builder*, July 30th, 1853.)

At about the same time, Mr. Calla, engineer and contractor of Paris, subjected two hollow bricks to a weight equal to a column of 2,490 feet of bricks of the same description, and they passed the trial with perfect success.

In the fall of 1852 the Great Western railway company of France erected, with hollow bricks, in the depot of St. Lazare, Paris, a succession of arches covering two and one-half acres, for the purpose of landing passengers and freight. The arches, which are supported by iron columns and girders, are unusually flat and thin, being 16 inches in the curve only, 8½ inches thick, with a span of 16½ feet. As soon as built a heavy carriage traffic began on them, without the slightest deflection. Previous to commencing the work, the company had submitted the bricks to the most severe trials.

Although imperfect in former times, as before stated, Borie's hollow bricks were rewarded with a prize medal in the International exhibition of London of 1851, and with two gold medals in those of Paris in 1855 and 1867, besides premiums obtained in the exhibitions of Sheffield, Amsterdam and others. A last and not least advantage of Jules Borie's improved hollow bricks, is that they can be manufactured as cheap as good common solid bricks.

For further particulars apply to Jules Borie, civil engineer, postoffice box 633, Oakland, Cal., and Junction City, Kansas.

Alpine County—Its Mines and Resources, Past, Present and Future.

[For the PRESS by VICTOR HARLAND.—No. 1.]

Alpine county, as its name indicates, is situated among the grand old monuments of Nature's rearing; among the world renowned mountain chains of the California Sierras, and upon the eastern slope. Our means of communication with the outside world are, however, most excellent—direct communication from your city being afforded us, in this age of lightning trains and progressive enterprise, in 26 hours.

The principal industries within the county are agricultural, timbering and mining. Of the latter it is my intention to treat, and, if possible, to place before the many readers of your widely circulated journal, and the public generally, the advantages of Alpine county as a mining region; together with the disadvantages under which we have labored in the past, which latter, however, are destined to give way before the ever advancing science of mining so successfully prosecuted by our mining men of the present day.

There are several

Mining Districts

Within the county, the most prominent of which are Silver Mountain and Monitor districts, and which, in the days that are past, were the scenes of active and busy life. Like many other mining localities in both California and Nevada, we have had innumerable difficulties to contend with, and which, for various reasons, have been prolonged to an extent that is unwarrantable and inexcusable in many instances. These reasons your correspondent will endeavor to analyze in general and in detail before closing the articles descriptive of the various districts and the mines situated therein.

Within the county and passing through four of the mining districts is a

Vast Mineral Belt

About eight miles in width, with a general, yet well defined course, northerly and southerly, and in the aggregate about 12 or 14 miles in length. The most casual observer, in passing through this belt, will not fail in noticing its boldness and magnitude, while the studious mining advocate and scientist will immediately observe its perfect adaptation for mineral purposes; and a careful examination will reveal the varied and prominent evidences of the mineral wealth here exposed. Among many of our notable men who have visited this region, we find the name of the late J. Ross Browne, who, in the course of his statistical information, paid this county a high tribute. The suggestions and directions from him and others of like note and experience, regarding deep working and an abandonment of

The Tunnel System

Were not heeded, and for years this country has been subjected to these worse than useless evidences of primitive conception in the form of surface tunnels, driven at a cost of thousands of dollars, where advantageous sites were easily obtainable for hoisting works and permanent shafts. Fortunately, however, the days of tunneling are over in this county, and now, at the eleventh hour, is inaugurated the system that should have been adopted at the time of the discovery and occupancy of these districts. Had this course been pursued heretofore our mines would now be adding their quota to the vast mineral productions of the coast, and the county of Alpine second to none as a region of mineral wealth.

The interest manifested by the Advance and Flint companies of Monitor, and the Exchequer of Silver Mountain district, has incited to action many other mine owners and prospectors here, and the universal opinion is, that from the present memorable year, an era of permanent prosperity and success will have dawned upon the county, greater than ever before realized since its discovery. Among the

Many Difficulties Experienced

Here is the lack of proper and economical roasting furnaces for the reduction of our ores. Worthless articles, of many descriptions, and bearing numerous titles, have been foisted upon the mining public as the one great thing needed. Expensive in erection, and worthless in action, they have paralyzed the interests here to a greater degree than perhaps anything else that we have been compelled to contend with, and are to-day standing monuments of fraud, and a mournful lesson to the directors and stockholders of the various companies whose pockets have been depleted by the erection and attempted use of these useless piles of brick and stone. It is self-evident to any one that sufficient caution in this particular was not observed by those whose duty called them to the front as superintendents and managers of the various companies, else these visionary monuments of uselessness would never have been erected. Our ores are refractory, it is true, but medium results have been obtained by raw amalgamation, and when a furnace or process not too expensive in working is shown to the public that will thoroughly and successfully treat our ores, no further apprehensions are needed regarding ultimate results from either quantity or quality of our ores. We want something that will terminate this battle with the baser metals, and once obtained, our future as a bullion producing region is not at all clouded. Our lodes are massive and well defined, and with the aid of well directed capital, furnished with one-fourth the uniformity exhibited on the Comstock, not only one, but hundreds of the lodes within this vast belt will prove conclusively to the promotors of such efforts that their labors will have not been in vain.

A SERIOUS FIRE.—We regret being called upon to record a serious loss which has fallen upon the Averill chemical paint company. On Wednesday morning, of this week, their store and office on Pine street was destroyed by fire and the stock on hand burned up. Although this is a severe loss the company do not on that account allow their business to be interrupted in the least. The office will be for the present at the factory, on Townsend street, near Fourth, and, as they have on hand there a large stock of paints and oils, customers can be supplied as usual without any delay. The Averill chemical paint company has been now so long established here, and their product is so well known and liked, that its many friends will regret to hear of the loss. The stock destroyed was partially insured.

A PRACTICAL BOOK.—There is shortly to be issued by Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome street, a work of interest to miners, entitled "A Practical Treatise on Testing and Working Ores," by Charles H. Aaron. This is a thoroughly practical treatise, of value to the scientific as well as the working miner. To the latter, however, it commends itself most highly, as it contains hundreds of practical hints on everyday work, and describes the methods and processes of working different ores with the most economical appliances to be used. It is one of the most practical works on mining which has yet been written.

IN the Hale & Norcross mine the foundations for the new machinery are steadily progressing. The coping stone is nearly all in place, and the huge pieces of machinery are being prepared for the occupancy of their proper positions. The old pumps and columns have been all extracted from the shaft, ready to place the new ones.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING JULY 4TH, 1876.

BARREL TAPS AND FAUCETS.—Elisha T. Barlow, S. F.

LASTING MACHINES.—William Bayhouse, Boise City, Idaho.

STRAP HINGES.—Abraham C. Buffington, Cambria, Cal.

BRACKETS FOR HOLDING LAMPS.—Henry Campbell, S. F.

CHURNS.—James Root, Woodland, Cal.

COOKS AND FAUCETS.—Amos C. Springer, S. F.

ADJUSTABLE WATCH KEYS.—Henry Bequelin, assor. to S. Farjeon and Dinkelspiel, S. F.

AMALGAMATING APPARATOS.—Thomas W. Irving, Port Madison, W. T.

JOURNAL BOXES.—Geo. I. Schoenberg, S. F.

GANG PLOWS.—Reissue—F. A. Hill, San Leandro, Cal.

DESIGNS.

CENTER PIECE.—Samuel Killett, (two cases) S. F.

FOR WEEK ENDING JULY 11TH, 1876.

LAMP EXTINGUISHER.—Lucien Honriet, San Jose, Cal.

BEE HIVES.—Orson A Davis, Sacramento, Cal.

SAW CLAMPS.—Joseph Shelly, Mariposa, Cal.

DAMPERS FOR RETURN TUBULAR BOILERS.—Joseph Enright, San Jose, Cal.

RAILWAY TUBES AND CARS.—Andrew S. Hallidie, S. F.

MANUFACTURING COFFINS.—William O. Day, S. F.

SOLDERING CLAMPS.—Ferdinand C. Smith and Charles E. Smith, Portland, Or.

DESIGNS.

CENTER PIECE.—Samuel Killett, (three cases) S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency the following are worthy of mention:

ALLOY FOR ANTI-FRICTION METAL.—Isaac Schoenberg, S. F. This alloy is more especially valuable for journal boxes, especially upon railway carriages and wherever there is a great amount of wear. These boxes are usually made from brass or some alloy forming yellow metal, and must be turned to fit the journal in order to be serviceable. They easily become heated if they fit too tight and they should not be wide enough sidewise to become cracked and split open. The improved alloy is formed into a box by pouring it around a shaft or journal which is properly luted into the outer iron box. No finishing is necessary, as the journal will gradually wear itself into perfect contact, but this wear takes place slowly, and the journal may travel over 3,000 miles of railway without the box being ground to a perfect bearing. This, however, is not prejudicial, as the metal seems to unite all the valuable qualities of anti-friction without being so hard as to cut or wear the journal. It is also tough, and if the journal should happen to bear upon the sides instead of the bottom, there will be no danger of the box becoming split open. This peculiar alloy is made of copper, tin and zinc, in certain stated proportions.

HINGE.—A. S. Buffington, Cambria, San Luis Obispo county. This inventor supplies what he calls a self-lubricating butt or hinge. The improvement consists in the employment of a metallic washer between the knuckles which comprise the joints of butts and hinges. The washer can be made of brass, copper, zinc or other soft metal that will not oxidize or rust, and adhere to the iron or steel knuckles, and the wearing of which will serve as a lubricator to prevent the joints from becoming stiff and squeaking. This improvement is more especially useful for strap hinges, such as are used on butter boxes. These hinges are exposed to wet and corrosion by contact with the salt employed in the butter, and soon wear out and break off by reason of this corrosion, and if one hinge becomes broken the box will almost certainly be destroyed before it reaches its destination. The inventor thinks that this construction will prevent, in a great measure, the breaking of the hinges by corrosion in the manner described.

ADJUSTABLE WATCH KEY.—Henry Bequelin, San Francisco. This invention is an improvement on that class of watch keys which are made to be adjusted to fit any sized post. It consists in the formation of two flat plates which are riveted together to form the thumb piece or handle. The stem is formed by a continuation of these two pieces drawn down to the proper shape, and the socket is formed one-half in each part of the post. The stem is made in the form of a double frustrum of a cone, and a sliding ring is fitted to the part of the cone nearest the handle. By sliding the ring back the parts of the stem are allowed to open, and they are closed by moving it forward. A groove is turned around the ring to receive a loose ring, by which to attach the key to a chain or key ring.

TAP FOR FAUCETS.—Amos C. Springer, San Francisco. This invention relates to a novel construction for a tap for barrels and other containing vessels, and it consists of a socket which is screwed into the barrel permanently, and has a screw valve which can only be opened by the faucet after the latter reaches its seat, and this valve must always be closed before the faucet can be removed, thus preventing all opportunity for leakage.

CLAMPS FOR BOOTS AND SHOES.—Wm. Bayhouse, Boise City, Idaho. The lever lasting clamp is an improved mechanism for lasting boots and shoes, and comprises a means for holding a boot in position, while the edge of the leather is seized by pincers operating in a novel manner, and drawn into place by means of a peculiar and powerful lever, which is mounted upon a fulcrum with a screw adjustment.

General News Items.

Two important South Wales collieries have stopped.

THE city training ship *Jamestown* will shortly start on a cruise to the Sandwich islands.

GENERAL T. W. BENNETT, recently nominated by the President for Governor of Idaho Territory, declines the office.

THE deaths in New York last week were 1,298, against 858 for the previous week. The increase is attributed to the very hot weather.

EVERY man who has more than three pimples on his face at the present time is suspected of having the small pox.

THIRTY deaths have already resulted from the explosion of the boiler of the *Thunderer*, and half of the wounded are not expected to recover.

THE failure of McLagor & Smith, New Haven, iron founders, is announced. Liabilities, $1,000,000, of which $880,000 is secured.

A LONDON *Times'* Paris dispatch says the Chamber of Deputies has unanimously passed the bill authorizing the International exhibition of 1878.

THE Postmaster-General has been informed by Commodore Vanderbilt and Colonel Scott, that the fast mail service will be discontinued on and after Saturday next.

OWING to the business depression, employers in England propose a reduction in wages or an increase in working hours of mill operatives and miners, who in some districts are preparing to resist. Great strikes are apprehended.

THE act amendatory of the Bankrupt act has passed both Houses and gone to the President. As enacted, its effect is simply to allow bankrupts to apply for discharge from their debts at any time prior to the final decision of the case, instead of limiting them to one year; and to provide, also, that voluntary assignments under State laws shall not be a bar to the discharge of bankrupts, if made in good faith for the equal benefit of all creditors. These amendments apply to pending as well as future cases.

THE RAINBOW LEAD.—This lead, says the *Butte Miner*, is probably the largest in Montana Territory. It lies to the north of Butte, and is in extent, as far as known, taking from the point farthest east to that of the west, nearly three miles, and along this entire line can the lodge be traced by its outcroppings which in places show a width of from 10 to 12 feet of vein matter. As yet, the amount of work done upon it is inconsiderable. Upon the west end, a shaft of 77 feet has been sunk, which shows the vein a very wide one so far. But one wall has been discovered, and the ore showing is from five to seven feet wide, with an assayed value of from $50 to $150 per ton. To the east of this shaft at various points, holes have been dug upon the vein from 10 to 12 feet deep, and the ore taken out has been of a fair quality, about 20 tons of which are now being milled. On spots upon this lode very rich rock is taken from the surface, and it is expected that from the sales of this the cost of development will be defrayed. From the present showing it is impossible to give the true character of this vein, but it has every indication of being a very extensive and inexhaustible lead, and at no very distant day it will be demonstrated that this lode is of such compass, and the ore of such quality that a score of mills will be required in order to work it, through its entire length.

THE new pan mill of the Consolidated Virginia mine is getting well under way and will soon be ready to run. The frame is up, ready to inclose. The framework of the platforms on which the pans and settlers will stand is completed, and several of the pans are already in place. The boilers are set and the pits dug for the foundations of the engines. Much of the other necessary machinery is already on the ground.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

HENRY NELSON, Merced Falls, is requested to address this office.

CLOSE observers of humanitarian tendencies must have noticed that nothing is so common among the working classes, male and female, as old ulcers, which resist all ordinary applications for their removal. GLENN'S SULPHUR SOAP will remove them. Sold everywhere.

Superior Photographs.

To be sure of a good picture, you have only to patronize G. D. Morse's Palace of Art, at No. 417 Montgomery street, S. F. The publishers of this journal have patronized Mr. Morse for many years, and do not hesitate to say that his pictures are not excelled by any we have seen produced in this or any other country. No one can ask for a better man to patronize than Mr. Morse. He is affable and respectful to all.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—California.
O. W. MCOREW—Santa Clara county.
J. M. MCARTHUR—Los Angeles, Santa Barbara, Ventura, San Bernardino and San Diego counties.
A. C. KNOX—El Dorado county.
F. A. SCOFIELD—Sonoma county.
C. N. WEST—Santa Cruz county.
CHAS. E. SAJOUS—Philadelphia.
A. C. CHAMPION—Tulare, Fresno and Kern counties.
RICHARD RULE—Nevada.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver. 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price $2.50 coin, or $3 currency, postage free. Published and sold at this office.

BOUND VOLUMES of the MINING AND SCIENTIFIC PRESS from Jan. 1st, 1864, are for sale at this office at $5 per volume, two volumes a year. Unbound at $3 per volume.

The Mechanics' Fair Daily.

This journal, printed and issued in the Pavilion of the ELEVENTH INDUSTRIAL EXHIBITION, and circulated free, will be a superior publication. It will contain all OFFICIAL INFORMATION during the Exhibition, commencing Aug. 8th, 1876. ITS ILLUSTRATIONS will furnish accurate views of NEW INVENTIONS AND MACHINERY.

The volume will give a substantial and readable RECORD OF THE FAIR, quite valuable for reference and preservation, in addition to a goodly variety of other reading matter, daily, embracing GRAPHIC PARAGRAPHS AND HUMOROUS INCIDENTS, making altogether a paper eagerly sought for (both in and out of the Pavilion) by nearly a QUARTER OF A MILLION OF READERS during the term of the Exhibition—a circulation reaching a greater number of different individuals than that of any publication yet issued.

We shall make a specialty of inserting ATTRACTIVE ADVERTISEMENTS, representing the leading firms in nearly EVERY BRANCH OF TRADE AND INDUSTRY on this coast, upon favorable terms, soliciting such as we believe will be most benefited by advertising in a well conducted, enterprising and everywise meritorious journal.

This beautifully illustrated sheet, issued upon such an occasion, will receive close attention, and its contents—both reading and advertising being original—will be closely scanned throughout.

THE IMMENSE PAVILION has been improved for the coming Fair. An unusually large amount of space for exhibits has already been engaged. Special exhibitions and new and attractive features will be introduced, calculated to make the Fair of 1876 a GRAND SUCCESS.

Orders for advertising, sent in early, will receive careful attention.

The undersigned, publishers of the MINING AND SCIENTIFIC PRESS, have successfully issued a popular daily in the Mechanics' Fair during seven Industrial Exhibitions since 1864, and we are now confident of making the coming volume surpass all its predecessors in its standard of value as a reading journal of art and information and a medium of first-class business announcements.

We have been awarded by the managers of the Exhibition the EXCLUSIVE PUBLISHING AND ADVERTISING PRIVILEGES of the Eleventh Industrial Exhibition, and are determined to accomplish a work creditable to the MECHANICS' INSTITUTE, to OUR PATRONS, AND TO OURSELVES.

DEWEY & CO.,
Publishers and Patent Agents, No. 224 Sansome street, S. E. Cor. of California, S. F.

Thanks for Prompt Attention.

STOCKTON, June 26, 1876.

Messrs. Dewey & Co., S. F.:—

I have received the patent for my invention in wagon brakes, which you prosecuted for me; patented May 11, 1875—No. 163,046. Thanks to you for your prompt attention to the case; you will hereafter be my attorneys in such cases. I recommend all inventors on the Pacific coast to give you a call, which I think they will never have any cause to regret. Very truly yours,

GEO. G. BUCKLAND,
Stockton, Cal.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect **July 1st, 1874**, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

PATENT FOR SALE.

Improvement in Wagon Brakes; is alika good for buggy and the heavy wagon. A splendid opportunity for some person with little capital. The inventor having other business, will dispose of his United States right. For particulars, address

OEO. O. BUCKLAND,
Milton, Calavaras Co., Cal.
Pat. May 11th, 1875.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Antilles Mining Company—Location of principal place of business, San Francisco, Cal.

Notice is hereby given, that at a meeting of the Directors, held the seventh day of July, 1876, an assessment of 20 cents per share was levied upon the capital stock of the corporation, payable immediately, in U. S. gold coin, to the Secretary, at his office, No. 207 Sansome street (third floor), San Francisco.

Any stock upon which this assessment shall remain unpaid on August 16th, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, September 8th, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

H. M. MORGAN, Secretary.
Office, 207 Sansome street, San Francisco, Cal.

Cherokee Flat Blue Gravel Company— Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment, No. 36, levied on the eighth day of June, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
A Caselli	17	4008	$230 40
Mrs Mary W Farrington	35	144	7 20
Mrs E M Walton, balance of certificate No. 21	128	shares sold for assessment No. 35	81	73	3 65
George W Ramage, balance certificate No. 36, 320 shares sold for assessment No. 35	83	235	11 75

And in accordance with law, and an order of the Board of Directors, made on the eighth day of June, 1876, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, room 13, No. 328 Montgomery street, San Francisco, Cal., on Saturday, the fifth day of August, 1876, at the hour of two o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

O. H. BOGART, Secretary.
Office, Room 13, Safe Deposit Building, San Francisco, Cal.

Office South Comstock Gold and Silver Mining Company. NOTICE.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of trustees and the transaction of such other business as may be presented, will be held on Monday, the 21st day of August, 1876, at two o'clock P. M., of that day, at the office of the company. Transfer books will be closed on Wednesday, August 16th, 1876, at three o'clock P. M.

J. M. BUFFINGTON, Secretary.
Office, Rooms 3 and 4, No. 311 California street, over Ætna Insurance Office, entrance 309 California street, San Francisco, Cal.

Kearsarge Consolidated Quicksilver Mining Company. Principal place of business, San Francisco, Cal. Location of works, Lake Mining District, Lake County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the first day of July, 1876, an assessment of fifteen cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, No. 10 Stevenson Block, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 28th day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 16th day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale

JAMES MCHAFFEE, Secretary.
Office, Room 10, Stevenson Block, San Francisco, Cal.

Mariposa Land and Mining Company of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixth day of July, 1876, an assessment (No. 6) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 9 Nassau street, New York.

Any stock upon which this assessment shall remain unpaid on the seventh day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the second day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.
Office, Room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Office of the Tintic Milling and Mining Company, San Francisco, Cal., July 14th, 1876. The annual meeting of the stockholders of the Tintic Milling and Mining Company will be held at the office of the company, No. 310 Sansome street, San Francisco, on Monday, August 14th, 1876, at two o'clock P. M., for the election of directors for the ensuing year, and the transaction of such other business as may be brought before the stockholders. By direction of the Board of Directors,

H. CLAY MILLER, Secretary.
San Francisco, July 14th, 1876.

Umpire Tunnel and Mining Company of Utah. Principal place of business, San Francisco, Cal. Location of works, Big Cottonwood District, Utah.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 23d day of June, 1876, an assessment (No. 5) of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, 605 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 24th day of July, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 14th day of August, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. W. DAVIS, Secretary.
Office, 605 Montgomery street, San Francisco, Cal.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

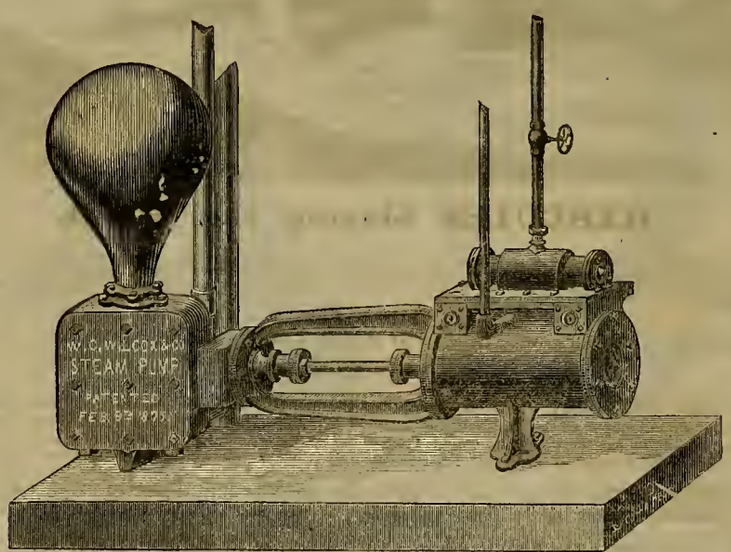
Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.



We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which these pumps are adaptable, such as

RAISING WATER FROM MINES

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

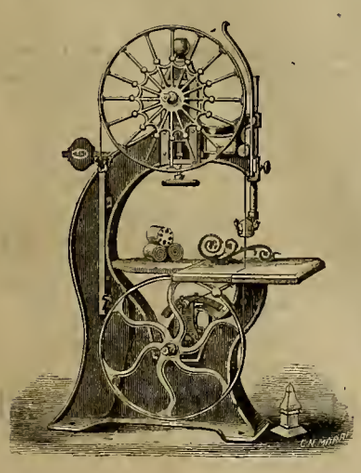
Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim.** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

PACIFIC MACHINERY DEPOT,



H. P. GREGORY & Co., Nos. 14 & 16 First Street,

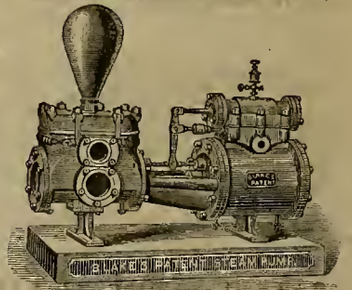
Pure Oak Tanned Leather Belting,

Perin's French Band Saw Blades,

Planer Knives,

Nathan & Dreyfus' Glass Oilers, and Mill and Mining Supplies of all Kinds.

BLAKE'S PATENT STEAM PUMP.



Over 8,500 in Successful Use in the Unite Statss.

HERCULES POWDER.

HERCULES Slaying the Giants.

Hercules, the son of Jupiter and Alcmena, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion, he was sent by Eurystheus to execute a very great task, when he found himself opposed by several Giants, among whom were the powerful Gisut Geryon, Eurytion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this powder one-half the time is saved that is lost by using any other strong Powder, before you can resume work after a blast.

2. UNIFORMITY.—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.

3. SAFETY—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No Powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.

4. CARTRIDGES.—It is well known that nitro-glycerine has a tendency to decompose by volitilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectually is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally used for cartridges.

5. ECONOMY.—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per cent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. { Hercules X X No. 1, for extreme hard rock. / Herculee X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself:*

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D. 1875.

Present:—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court; Honorable Lorenzo Sawyer, Circuit Judge.

THE GIANT POWDER COMPANY vs. THE CALIFORNIA POWDER WORKS, ET AL., *In Equity, No.* 1,233.—The Court having, on the 22d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said bill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said bill having expired, and the default of said complainant to amend its said bill having been duly entered, and the Court having on the sixth day of October of the said term and year, on motion of C. R. Greathouse, Esq., solicitor for defendants, M. A. Wheaton, Esq., Solicitor for complainant, being present, in open Court, and declining to amend his said bill of complaint, he having elected to abide by his said bill of complaint as filed in this cause, ordered that a decree be entered herein dismissing said bill.

Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said bill be, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended.

October 18th, 1875.

(Signed) LORENZO SAWYER,
U. S. Circuit, Judge Ninth Circuit.

ENDORSED:—Filed and entered, October 18th, 1875.

L. S. B. SAWYER, Clerk.
By J. F. O'BEIRNE, Dep. Clerk.

Sold by THE CALIFORNIA POWDER WORKS, 314 California Street, San Francisco, Cal.

Also, all grades of Black Powder, Fuse, Shot, Caps, Etc.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, JULY 29, 1876.

VOLUME XXXIII Number 5.

Improvement in Condensers.

We give on this page a sketch of a patent condenser for cooling heated vapors or fumes, invented by Charles B. Dahlgren. The principle consists in constructing the condensing chamber either partially or wholly of an absorbent material, which is kept constantly saturated with water so as to produce a refrigeratory effect inside of the chamber by the evaporation of the water from the surrounding surfaces. An application of the improvement may be made in connection with an ordinary retort for separating quicksilver from gold and silver amalgam.

In the base of the retort, which can be constructed in various ways, is an open basin or retort, in which is the amalgam to be retorted. Under the basin is the furnace, etc. Upon the base is constructed a simple framework which is capable of supporting a housing, which is made of canvas or other absorbent material. In the base is a channel which extends entirely around the retort, and this channel is kept filled with water. The housing is so suspended or adjusted that its lower edge will enter the water in the channel and thus prevent the escape of any of the vapors. Above the housing are perforated water pipes arranged so as to allow a constant spray or stream of water on the housing and thus keep it saturated. The surplus water will flow down the sides of the housing and be caught in the channel into which the lower edge of the housing dips. A waste pipe carries away the surplus water.

The evaporation of the moisture from the housing will make a refrigerating action inside the chamber, inside of which the fumes are generated or delivered, so that they will be condensed inside of the housing and flow down its sides into the channel. A condenser of this kind can be applied wherever it is desired to condense vapors or fumes. It can be cheaply constructed, while it is claimed that its action will be superior to that of any of the ordinary methods of condensing vapors.

Quicksilver.

Quicksilver is a little firmer this week than last, when it fell to 41 cents per pound, the lowest price for some years. This week it may be quoted at from 43 to 45 cents. The continued depression in the price of this article is a very good thing for the ordinary metal miner, but not for the one who delves for quicksilver. In fact, a number of small quicksilver mines have been compelled to shut down entirely on account of the low price of the product.

The large mines, however, with their complete equipment for reducing the ore on a large scale, continue to keep up their production, and some of them are even putting up new furnaces, etc., showing that at the present price they are able to make some profit. The mines, however, which were run with a few retorts when quicksilver was high find it difficult to keep up expenses, and many of them have shut down. At the same time the excitement of prospecting for quicksilver has entirely passed over, as the inducements held out are now not as great as they were when not many months since, quicksilver was $1 65 per pound. In Napa, Sonoma and Lake counties there was for a year or so an excitement on the subject which took even the farmers away from the plow, and everybody was wild on cinnabar. At that time it was thought that quicksilver would go to $2 per pound, and some of the tailings mills in Nevada were compelled to shut down. Now, however, the gold and silver miners have the best of the situation, as the production of quicksilver became so great as to reduce the price greatly. It can be bought now for less than one-third the price it sold for one year ago. When at a dollar and a half a pound many mines were working on one per cent. ore, or even less, but at the present price ora must be better than that unless everything is on a large scale.

Owing to the depreciation of silver and the want of plenty of trade dollars in Pioche, business matters are very dull.

The Harbor Commissioners' New Tug-Boat.

The 21st of this month witnessed the launch of the last new tug-boat built by Messrs. Hanson, Ackerson & Co., the machinery for which was made entirely in the East, brought here and placed in the hull, which was built here. As an agreeable contrast to this undertaking, as far as home industries are concerned, we present some particulars of the machinery for the new tug shortly to be built for the Harbor Commissioners, the designs of which were prepared in this city, and the whole work of which will be done here. Estimates are shortly to be called for in this work, so that the details given herewith will be of interest to our machinists, who will soon have an opportunity to compete for the contract.

A three-bladed gun metal propeller is required, driven by a pair of high pressure, direct acting engines, fed by a tubular marine boiler, so arranged as to be entirely operated and controlled from the deck—an obvious improvement upon most of the tugs now at work in our harbor.

The steam cylinders are 18 inches in diameter and two feet from center to center of engines. The valve boxes are cast solid to the cylinders, with stuffing boxes, through which the rod operating the slide valve and the expansion blocks works. The cylinder is bolted on to the top of the upright frame, which is turned up, with a stuffing box cast on, and thus forms the bottom cover of the cylinder. All parts are solidly bolted to this frame, which, with the bed plate and crank sheft journals is solidly bolted to the foundation timbers of the boat by four one and one-half inch bolts and six one and three-quarter inch bolts.

A CHEAP CONDENSER.

The expansion cut off attachment to the valves is one of the most noteworthy points in the design of the engines. This is operated by an independent eccentric. The adjustable blocks on the rod working on the back of the valve enable the steam to be cut off at one-tenth of a pound stroke, and worked expansively on any intermediate grade up to full steam. In carrying out this most desirable economy in the use of the steam, the most serious objections to similar arrangements for this purpose are here overcome, the most important being the great friction almost always accompanying one valve surface working upon another, overcome in this case by admitting steam on each side of the valve, termed the equilibrium adjustment; the other point being the great necessity for all work of this class to be as simple and durable as possible. However, by a compact arrangement as explained on the detail plan, the three eccentrics for each engine are brought into a comparatively small space, and the reversing gear, the most formidable arrangement to those uninitiated with the details of marine engineering, is brought under perfect control by a single hand lever operated from the deck.

The engine frame is cast iron, including in one casting the bed plate, boxes for crank shaft, bottom of steam cylinder, to which the cylinder is bolted, and the upright frame.

The crank shaft, crank pins and cranks are forged in one solid piece of wrought iron. The links, levers, pins, etc., forming the operating and reversing gear for the valves, are of wrought iron, the working parts being steeled. Piston rods, iron. Piston six inches wide with six grooves turned in for steam-tight rings. A powerful force pump is attached to each engine. The cranks are at right angles. The working surfaces of the main portions of the engines are of solid gun metal, and the boxes for the levers and pins are lined with Babbitt metal. The steam supply pipes are eight inches in diameter and the exhaust pipes seven inches in diameter, and are coupled to the steam chests close in to the cylinders, forming a very compact arrangement, and also acting as a stair and connection for the two cylinders, coupling them firmly together.

The designs are unique and well proportioned throughout, and the uniformity observed in having all similar pieces of the same construction, forms a great saving when repairs are necessary, as may be remarked on many of the tugs running in the harbor where scarcely

INDIAN STONE IMPLEMENT.

any two pieces are alike. In the present case, for instance, either of the cylinders may be substituted for the other, or the top may be used as the bottom, thus simplifying considerably the work of pattern making, the first cost for construction and that which may eventually occur for any alterations or repairs at any future time. Ample space is provided for coal bunkers and water tanks under and on each side of the engines and boilers. Convenient accommodation is provided in the cabin arrangements, which may be used as temporary quarters at any time by the engineer and crew.

The proportions and capacity of this new tug warrant the belief that it will prove the equal if not the superior of many of the powerful craft of this class which form the working power around the wharves and along the water front. Those immediately interested in the machine business in this city, and who feel the pressure of the somewhat slack season, should go and examine these plans and stipulations for themselves as soon as the advertisement from the board calls for estimates and bids, which will be shortly. It is understood that the terms of payment will be 75 per cent. as the work progresses, or the certificate of the supervising engineer, and the balance on completion of the work. The boat will be used in the service of the State Board of Harbor Commissioners.

Stone Implements.

We give on this page representations of two of the stone implements found in the Bridger basin of Southern Wyoming, to which we referred in a recent issue of the Press. Two views are shown, half size. This is a modern stone implement of gray quartzite, a simple flake from a drift-pebble of the Uintahs. It is called by the Shoshone Indians a "teshoa" and is used by them as a scraper in dressing skins.

Machinery at the Fair.

Although the social features of the Mechanics' Institute fair are the most attractive to a majority of people, the industrial features are of vastly more importance. While the attractions of the art gallery, the music, etc., draw their crowd, the machinery in motion has an interest to many others which they seldom have an opportunity to gratify. The periodical occurrence of these exhibitions affords to many of our citizens the only chance they ever have to examine the details of various mechanical devices, and without this feature they would care little for the fair.

A laudable curiosity of this sort should be gratified, and it rests with our manufacturers and those engaged in industrial pursuits to fulfill the desires of the managers and the public and make as full a display as possible. The foundry and machine shops have not this year the excuse of last, busy times, to offer, as work has slackened up in many of them, and a fine opportunity is now offered to exhibit to the public, where they can be examined, samples of the handiwork of our artisans.

We have no means of knowing, as yet, how much of a show will be made at the fair by our mechanics, but trust it will be a good one. If they neglect the opportunity here offered it is to their discredit and disadvantage. Agents of Eastern ready made machinery of all kinds, who can exhibit at comparatively little expense, will, no doubt, take care to make as good displays as possible, and as many persons form their opinions more on what they see than what they hear, the impression will be formed that our own mechanics cannot compete with the Eastern ones.

This is far from being the case, but our mechanics should see to it that no such false impression should get abroad. It is impracticable to put up heavy mining machinery in the pavilion, as none of it is made except to order, and the owners want it as soon as it is made. But machinery of ordinary kinds could be manufactured, finished neatly and displayed at the fair, which would show visitors what we can do here. This could be sold afterwards, and even if it does bring a lower price than when new, the advertisement of the particular firm who made it will more than compensate for any loss occuring in that way.

Last year visitors at the fair had no cause for complaint in the exhibit of machinery, as nearly if not all the space allotted to it was filled. This year it will be more of a special department than heretofore, as it is to be partitioned off from the main body of the pavilion.

We take occasion to urge our foundrymen and machinists to do all in their power to make the mechanical department of the exhibition a credit to the city and State. They are abundantly able to do it if they put their shoulders to the wheel. Friendly competition is beneficial to all concerned, and it looks discreditable to see a single exhibit of any special article where half a dozen similar ones should be. Industrial fairs require support, not only from the general public but from those in whose interest they are held. When the mechanics get up a good display the visitors are always forthcoming, and we hope the exhibit in this line this year will be equal, to if not better than the last.

Postage on Printed Matter.—The bill restoring the old rates on printed matter has become a law, and is already in operation. Third-class matter is partially defined to be "transient newspapers and magazines, regular publications designed primarily for advertising purposes, or for free circulation at nominal rates," which is subject to postage rates of one cent for every two ounces, and one cent for each additional fraction of two ounces. So far as transient newspapers, magazines, etc., are concerned, the law is the same as before the change made two years ago, i. e., one cent for two ounces or any fraction thereof; but the increased postage on the portion of third-class matter which comes under the denomination of merchandise is retained in the bill as established by the previous law—one cent for each ounce or fraction thereof.

CORRESPONDENCE.

Placer County Mines.

[By our own Correspondent.—No. 4.]

On Roach hill there are a number of good claims, among which the Phillips seemed to rank high in the estimation of some of the neighbors.

The Columbus is a good paying claim, having from three to four feet of cement, which is drifted ont and crushed. The front portion is good hydraulic ground. When visited only 10 out of 20 stamps were occupied, crushing about 30 tons per 24 hours, and paying somewhere in the neighborhood of $4 per ton.

The Strawberry Claim

In the flat above is said to have paid well formerly for drifting. It had recently been opened and worked by hydraulic. Watts & Co., the present owners, were well satisfied with the prospect. On the opposite side of Roach hill, Messrs. Burwell, Fuller & Pritchard have a gravel bank of 140 feet in hight, that has been hydrauliced altogether in the past two seasons only about four months, owing to scarcity of water. The claim is 1,400 feet square, with a front face of 500 feet, working from eight to 10 men. When on the ground, the bedrock had not been fully cleaned up, but judging from the way the undercurrents had paid, they were looking for a fine return.

Ont of the 25 claims that have been running, to say nothing of the large field of unoccupied ground, enough has been selected from which to form an idea of the vastness of the deposit here exposed for future industry, enterprise and capital.

I understand that Merrill & Co., of San Francisco, had located

An Asbestos Claim

Of some 6,000 feet in length, within one mile of Iowa Hill, three and one-half tons having been taken to the city and fully tested. Owing to the fact that it is one of the best known nonconductors of heat, they use it for felting, roofing, fire brick and some other purposes.

It is found here in much larger masses than usual, running in veins smaller or larger through the serpentine, and bulging out occasionally in bodies of considerable size, where it can be had in quantities, for shipment.

Besides the silken, fibrous form, from six to 12 inches in length, there are other varieties, grading off into the earthy common spar, or some form of talc or steatite.

Some fine specimens may be seen below Cape Horn, near Colfax, but whether sufficiently abundant for mining is yet to be determined.

Near this on the trail is a conglomerate rock, containing washed gravel that must be of very ancient date, for it has the appearance of having been tilted up, after stratifying similar to the slates and other stratified rocks.

The Rising Sun

At Colfax, had just made one more successful run about the time I was there, taking out about 400 ounces within 15 or 20 days. For the past few months it has not paid its regular dividend, but no assessment has been necessary, as it has been able to supply the means for running expenses while the mine was being put in shape for future profitable working.

Gold Run and Dutch Flat Mines.

As the Gold Run and Dutch Flat mines had recently been so fully and favorably written up, special notes from these points were deemed almost superfluous. They cannot be said to suffer from lack of capital. There were many vast enterprises going forward that were either rich in present results or full of promise for the future. When these, and others contemplated for properly working along these deep, rich channels from bedrock upwards are fully completed, the gross yield will be enormous, and the net profit on investments increased in even a greater ratio. It is true that much of the surface has been skimmed, but the richest of the cream is believed to be left.

Mr. J. J. Brady, of Dutch Flat, has made an

Improvement in Operating Derricks,

Which appeared worthy of a place in a journal so generally read by miners and mechanics. The principal object is to save the wear and tear of ropes over the boom-arms. A hole is bored three inches in diameter from the foot of the mast centrally for 12 feet in length, and another obliquely eight feet long from the face of the mast, connecting with the former, a sheave being fixed at the connection of the two and also a carriage with a sheave in it, placed on the face of the mast for the purpose of directing the ropes centrally through the oblique hole. From the carriage sheave, as I understand it, the rope works as in any other derrick. The spindle on which the mast turns is five and three-fourth inches in diameter, with a hole through the center of the same size as that in the mast, and works on a foot block of cast iron, through which the rope passes on to the foot block sheave. Much time is said to be saved by the appliance. For instance, in the form in general use, after unloading from one point two-thirds of the distance has to be retraced to receive a load from the opposite point. In this arrangement no retracing of steps is necessary, but the derrick continues after unloading directly on the same course to any place required.

The Green Valley Mines.

About three miles from Alta, and nearly 2,500 feet below the track of the C. P. R. R., on the North fork of the American river, there is a narrow little valley, a mile or so in length, in full view from the passing cars.

Early one bright morning I let myself down into this deep gorge by a comparatively good winding trail of some two miles in length, to find the miners all busy at work.

The first claim reached was that of the Green Valley blue gravel company, incorporated in San Francisco, and holding a U. S. patent for 90 acres of gravel deposit, some of which seemed to be of recent date, and other portions perhaps much more ancient. There has probably been a slide at one time from the mountains, forming a dam in the river and also a bar, at the same time changing the course of the channel once at least, if not oftener.

On a large bar with a depth of gravel from 60 to 80 feet, reminding me much of Gold bar on the Middle fork, the company were sinking a well timbered shaft 4x8 feet, and, as informed by Mr. S. V. Souder, the superintendent, were passing through quicksand and would soon reach the gravel near the bedrock.

It is stated that some strata of this deposit prospect well and that as high as $10 per carload had been taken out at the lower part of the bar, so that very fine results are anticipated on completion of shaft. In the meantime a tunnel is being run from near present workings through the outer rim rock with the view of striking another and possibly an older channel believed to be not more than 150 feet distant. Connected with the property is a saw mill run by water—turbine wheel—also a flume and ditch four miles in length, with a capacity of 3,000 inches of water.

The St. Louis,

At the lower end of the valley, is a good drift and hydraulic claim, the property of Messrs. Nova & Christian. They were drifting on a layer of gravel 30 feet above bedrock that was paying $2.50 to the wheel-barrow load. Some of the dirt in this claim prospects from 50 cents to $1 to the pan. Mr. Opel had just began work on a claim that had formerly paid well. He informed me that the Hayden Hill, on the opposite side of the river, had paid fully up to his expectation for the season, paying usual regular dividends, which vary from $600 to $1,200 every year, according to time of run or supply of water.

The "76" mine, a drift claim 1,100 feet front and half mile in linear extent, is located at

Shady Run,

Five miles above Alta. They struck good pay gravel last February, since which time it has paid expenses and good wages. They have a good and extensive deposit of quartz gravel, with some rich spots that yield as much as an ounce a day to the man, or $5 per carload. Prospect for the future promising. The Wild Yankee, a consolidation of 30 claims of 900 square feet each, near the above but supposed to be in a different channel, has been opened by a tunnel 900 feet, and has turned out its thousands annually for 20 years. The latest run of three weeks paid Messrs. Wedgwood, Corlett and Brinks, the three owners, $480, in way of dividends over all expenses.

At Lost Camp,

In the neighborhood of Blue canyon, there is a deep channel of gravel 300 feet in width, that is said to be very rich, widening out in places to 2,500 feet. Mr. G. T. Bartlett ran two hydraulic claims here last season, but owing to its shortness the yield fell a little short of the usual average. Messrs. Bellows and Rathburn are drifting on the Boston, and they say their prospects are flattering. This claim has averaged in the past about $40 per day. No reason can be assigned why it may not do so again.

Some attention will now be given to the

Immense Lumbering Business

On or near the line of the C. P. R. R., from Dutch Flat as far as the summit of the Sierra Nevada mountains. Messrs. Towle Bros. turned out last year from two mills upward of 10,000,000 feet, and are cutting at present with three mills 60,000 feet per day. At their new Kearsarge mill, nine miles from town, two gang edgers are used, six saws each, Dicey's patent, which are easily regulated by lever and screws to divide the broad plank into the proper number and width of smaller sizes to economize the lumber. A narrow gauge railway had just been completed of 45 pound iron, operated by steam, reminding one of Clay Street hill in your city, about one-half mile of inch steel wire being employed. The cars, loaded with lumber from the mill, arise to the summit on a grade of three feet to the rod, and passing under the spool are lowered down a similar incline, 1,400 feet, to their main track, some seven miles long, which connects all their mills with the Central Pacific at Alta wood shed. In addition there is a large planing mill, completely fitted up with all the necessary machinery, among which of home invention may be mentioned two I. H. Small's planers, one of O. Bonney's band saws, and one of F. A. Huntington's shingle machines—all giving good satisfaction. This firm gives employment in their entire business to about 200 men.

The Bear River Mill,

Tillson & Carlin, owners, cuts with a Spaulding saw 16,000 feet daily, and for season of eight months usually about 2,500,000 feet. It is within a mile of Alta station. Some lumber is also dressed here, as one of Small's planers was seen on the premises. The Damsgard mill, two miles from Alta, manufactures per season about 1,200,000 feet.

S. Putnam, at Emigrant Gap, cut last year, with one mill, 750,000 feet, and 1,500,000 feet with another. In connection with the mill now running there is a planer and also

A Box-Making Machine,

or resawer of his own invention and construction, likely to prove valuable. I understand that the necessary preliminary arrangements have been entered into through the patent agency of Dewey & Co., with the view of soon taking the final proceedings for securing a patent. It is simple, safe and rapid. Boards, say of inch lumber, are first sawed the proper length for boxes, and then split into half-inch boards, by the new resawer, at the rate of 20,000 in ten hours, saving much time and labor. It seems to promise another stride in the right direction.

The Monumental Mill,

the property of Mr. I. Avery, of Emigrant Gap, and five miles distant, runs two large planers, manufacturing of flooring, rustic, ceiling and siding, altogether for season about 750,000 feet; daily cut of lumber, 20,000 feet; annual, 2,500,000. Messrs. Taylor & Pickins, of Alta, have also a mill six miles from the Gap, where there is usually turned out a million and a half feet every year, principally of sugar and yellow pine, and Mr. Geisendorfer, four miles above Cisco, supplies the C. P. R. R. company with ties and shed lumber, probably with an equal amount, making a total aggregate from Dutch Flat to Summit of about $20,000,000 feet.

I made

A Short and Pleasant Stay

With Mr. Hill, of the Summit house, its hospitalities being freely tendered, *pro bono publico*, or rather, as I imagine, through personal regard for Mr. A. T. Dewey, your energetic business manager. Here I breathed, for a brief period, the pure air, and reveled in the grand and delightful views from this aerial elevation, being, in more senses than one, nearer heaven than I soon expect to be, and then darted at lightning speed down an easy, winding grade, in full view of snow-capped peaks or grove encircled lake, some 14 miles to the rapidly rolling Truckee, and the flonrishing new town of the same name, situated in a beautiful little valley on its banks. You will probably hear something of its mills and manufactories in my next.

K.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANKS.]

I. Tourmaline, Rubellite, Indicolite.

The above are the varieties of tourmaline which are regarded as gems. Tourmaline is found assuming a variety of colors. Black and blue black are the most common—more rarely blue, green, red, brown and white or colorless. Some varieties are red internally and green externally. Sometimes one end of a crystal is red and blue, green or black at the other. Dichroic; streak uncolored, transparent, opaque, fracture sub-conchoidal, uneven, brittle, pyroelectric; crystalline form rhombohedral. Hardness, 7—7.5; specific gravity, 2.94—3.3; luster vitreous.

Some varieties fuse easily B. B., others are infusible, with fluxes. Some varieties give to the beads the characteristic color of iron. They all give the reaction of boracic acid. This reaction is obtained by finely pulverizing the mineral in an agate mortar, mixing with equal parts of a mixture of fluor spar and bi-sulpbate of potash; grinding the whole together until thoroughly mixed, and heating a small portion in a loop of platinum wire. By urging against it, by means of the blowpipe, the flame of an alcobol lamp, a green color will be imparted to the flame, characteristic of boracic acid. The experiment should be made in a dark room. Not decomposed by acids, but if freshly ignited, is wholly decomposed by sulphuric acid.

It is difficult to give the composition of a mineral which takes so many forms as tourmaline. In general terms it may be said to be an anhydrous silicate of alumina with various other bases, and always containing boracic acid.

Mineralogists have divided the varieties into several groups as follows: 1, magnesia tourmaline; 2, iron magnesia tourmaline; 3, iron tourmaline; 4, iron manganese, litbia, tourmaline; 5, lithia tourmaline. The black varieties are called tourmaline, schorl and aphrizite. The name tourmaline is probably derived from the name tounamal, given to the mineral in Ceylon, where it was first known. The red tourmaline is called rubellite from its color. The blue variety is named indicolite from a Latin and Greek work signifying indigo and a stone (indigo stone). Rubellite was called "lychnis" from the fact that its color was brightened by the light of a lamp.

A violet red specimen of rubellite from Siberia was analyzed by Vauquelin, and found to contain the following composition: Silica, 42; aluminum, 40; soda, 10; oxide of manganese and iron, 7. Total, 99.

Tourmaline possesses some remarkable optical properties. The transparent varieties are much prized for the manufacture of polarizing apparatus.

If two thin slices of tourmaline cut parallel to their axes are laid one over the other in one direction, they are transparent; if rotated on each other a point will be reached when they will be opaque. This property is taken advantage of in studying the nature of crystals.

Tourmaline is not considered a very valuable gem, but under certain circumstances it commands a high price. The value depends on color, purity and size. A crystal of rubellite in the British museum from the kingdom of Ava is valued at £1,000.

There are many locations of this mineral. The black is common in many parts of the world. In California, it is found black and green in the foothills and in the Sierra Nevada mountains. A remarkable locality is in the mountains between San Diego and the Colorado desert, where crystals occur six to eight inches in thickness. I have myself picked up fine specimens in the high sierras, near Mount Whitney.

Rubellite is found at Parie, Maine, in very fine transparent crystals, quite equal to any known. Fine specimens are found in Siberia and Brazil, the latter called sometimes Brazilian ruby, found also in Ceylon and Ava.

Indicolite is rare. That from Brazil is called Brazilian sapphire. A few specimens have been found in Siberia.

Fine specimens occur in New York, on Harlem hights, and at Goshen, Mass., in coarse granite.

Tourmaline may be looked for in granite, gneiss, syenite, mica, quartz, in dolomite, and in granular limestones.

II. Iolite, Syn., Cordierite, Dichroite.

This mineral is a silicate, of which the following is an average analysis:

Silica 49.62, alumina 28.72, oxide of iron 11.28, oxide of manganese 1.51, magnesia 8 94, lime 23.=100.30.

Crystalline form orthorhombic; hardness 7.75, specific gravity 2 56—2.596; color, various shades of blue, light, dark, sometimes smoky blue; streak uncolored, transparent, translucent. Fracture sub-conchoidal, shows pleochroism in a remarkable degree (pleochroism is the property of appearing of different colors when held to the light in different positions).

B. B. becomes opaque and fuses with difficulty. Only partly decomposed by acids, but wholly soluble after fusion with a mixture of carbonate of soda and potash. Becomes electrical by friction, and if heated assumes polarity.

Found at Cape de Gate in Spain, in an altered greenstone; in Greenland, in granite; at Arundal, in Norway. In Finland. A variety from Ceylon is found in small rounded masses of an intense blue color. Found also at Haddam, Conn.

This mineral is sometimes set as a gem but does not find many admirers. When cut to show its dichroism to advantage it is a noticeable stone and attracts some attention, more as a curiosity than from its beauty. A good specimen is worth from $10 upward.

Blue quartz is sometimes sold for iolite, but may be distinguished by its want of dichroism, its inferior hardness and electrical properties.

The name iolite is derived from two Greek words signifying "violet stone." Cordierite and dichroite, other names given to iolite, are called, the first from Cordier, a geologist, who first called attention to some of its optical peculiarities, and the latter from its dichroism.

The Silver Bill.

Following is the full text of the joint resolution for the issue of silver coin which has passed both houses of Congress and now goes to the President for his signature:

Section 1. That the Secretary of the Treasury, under such limits and regulations as will best secure the just and fair distribution of the same through the country, may issue the silver coin at any time in the Treasury to an amount not exceeding $10,000,000, in exchange for like amount of legal tender notes, and the notes so received in exchange shall be kept as a special fund separate and apart from all other money in the Treasury, and be issued only upon the retirement and destruction of a like sum of fractional currency received at the Treasury in payment of dues to the United States; and said fractional currency, when substituted, shall be destroyed and held as a part of the Sinking Fund, as provided in the Act approved April 17th, 1876.

Sec. 2. A trade dollar shall not hereafter be a legal tender, and the Secretary of the Treasury is hereby authorized to limit from time to time the coinage thereof to such an amount as he may deem sufficient to meet the export demand for the same.

Sec. 3. In addition to the amount of subsidiary silver coin authorized by law to be issued for the redemption of fractional currency, it shall be the law to manufacture at the silver mints and issue through the Treasury and its several offices such coin to an amount that, including the amount of subsidiary silver coin and of fractional currency outstanding, shall in the aggregate not exceed at any time $50,000,000.

Sec. 4. Silver bullion issued for the purpose of this Act shall be purchased from time to time at the market rate, by the Secretary of the Treasury, with any money in the Treasury not otherwise appropriated; but no purchase of bullion shall be made under this resolution when the market rate for the same shall be such as will not admit of the coinage provided without loss to the Treasury; and any gain or seignorage arising from the coinage shall be accounted for and paid into the Treasury as provided under the existing laws relative to subsidiary coinage; provided, that the amount at any one time invested in such silver bullion, exclusive of such resulting coin, shall not exceed $200,000.

MECHANICAL PROGRESS.

How to Build a Machine Shop.

The perfection of the shop often exerts a marked influence upon the quality of machine work. As all owners and workmen are interested in securing good shops, we extract a few points on shop building from a communication on the subject written to the *American Manufacturer* by J. H. Carpenter, a constructing engineer. He says: The lighter the machinery often the greater strength required; for instance, the vibratory motion of looms will throw a strong building which will be suitable for a large machine shop; reciprocating machinery will toss the walls off their foundations, which the heaviest weights and revolving machinery would not disturb. So it will be perceived that ponderous strength is not always the requisite; yet we see shops heavy enough for a bonded warehouse, which shake like a reed, notwithstanding their strength.

First, build walls of suitable strength for the weights; light walls, properly balanced and bonded, hold more than ponderous walls full of hats; have the walls, as far as possible, thrown in panels, using pilasters under the parts bearing the roof trusses; strengthen all large piers in the same manner. Now it is usually accounted that walls with pilasters are just as strong without them; this is truly the fact, as far as the bearing of the weights and superstructure is concerned; but they break all vibratory motion. Avoid ornament for the sake of ornament, for it is a blemish; but construct for strength, and if it makes a pleasing feature, use it to the best advantage. This is for the general form of the building; but ties, both ways, to a shop are as necessary as the walls, and can readily be arranged for in the tiers of beams.

The foundation is not the least part of a structure of this kind; it should be built so the bearings are perfect on the best of bottom, and the upper walls to rest on the centers of the foundations, securing a better both ways.

As to the roof and inner framing, it is far better to arrange to throw the weights to concentrated bearing than to scattered distribution, as this tends to break the effects of vibratory forces. Beams may be thrown over long spans by trussing them, and this I invariably do; putting them good distances from centers, in couples, and bracing them. This distance is governed by the class of machinery, but the beams generally come directly under the bearers of the machine, and render them solid, and keep them perfectly level; but to have one side of a machine on a beam and the other between the beams is very wearing to some machines, and they are never steady. Beams of this class seldom split, or settle, or vibrate when supporting machinery.

Another important item is the roof; this, if not balanced and supported on the walls properly, will produce vibration and bulging of the walls below, when in motion. Roofs are, as a general thing, too heavy for the walls supporting them; and it is best to use as little timber as possible, and substitute iron wherever possible, it being cheaper and many times better.

Shops need to be well lighted and ventilated; the windows wide and long. I make it a rule to arrange the radii of light so that machines in the center of the shop will receive as much light as those near the windows, and care should be taken to attain this. The remark, this is well lighted, by the superintendent of the works, shows his pleasure better than anything else. Dark shops spoil more work and good workmen than any other evil.

A NEW WEAPON.—The *Times of India* says: "A pistol that can kill at 500 yards has been patented by Captain Burton. The butt is that of an ordinary pistol; the barrel is that of a good rifle, cut short, but leaving sufficient 'turn' to send the bullet on its errand with the proper spin. The chief object is to send a rifle bullet at an enemy or at game without having to use the shoulder, especially when on horseback. To accomplish this the barrel is fitted with a steel handle to be grasped by the left hand, while the arm is extended as in archery. The recoil is scarcely felt; it does not affect the firer so much as the kick to the shoulder would. The pistol can also be used with one hand like an ordinary pistol. The inventor has also provided a patent safety bullet which will explode as a shell when it crashes against the bones of large game, but will pass through brushwood or through the skin of a wild animal like an ordinary ball. It will not explode if let fall upon its apex, but if fired into a box of ammunition it will blow up everything."

BLOWN CAST IRON.—The *Moniteur des Interets Materials* says that considerable attention has been given of late, in Belgium, to a method for to some degree refining cast iron previous to puddling, put in practice by Mr. Fernand Hamoir, of Maubeuge. The process consists of submitting the cast iron, at the instant it is tapped from the blast furnace, to a current of air from the same blast that is being supplied to the tuyeres of the furnace itself; the process is very rapid, and the apparatus simple and inexpensive, while the advantage obtained is, that the pig iron is so far refined that one charge more per 24 hours can be worked in the puddling furnace.

TESTING THE STRENGTH OF CHAINS.—The Cleveland *Trade Review* describes a very interesting and satisfactory exhibition of chain testing at the chain works of Abbott, Brew & Co. The apparatus used for the test was a hydraulic pump capable of exerting a testing power of 68 tons, and is worked by four men. The first chain tested was 90 feet long, the links being one and one fourth inches in diameter and about three inches long, each provided with a stud that increases the tensile strength of the chain one-eighth. This chain was tested under a strain of over 27 tons, without indicating weakness in any part, and it was regarded as entirely satisfactory by all parties witnessing it. This test being completed, links of a chain one and one-fourth inches in thickness and measuring 11¼ inches in length were put under pressure, to ascertain at what strain they would break. The pressure was continued up to 52 tons, when the heavy iron pin used in the test gave way and the test was carried no further. It was found upon examination that with one exception the links were unharmed; one, however, showed evidences of weakening under the severe pressure, and it is probable it would have parted at 53 tons. The links under the pressure had been stretched fully an inch and a half.

"CENTENNIAL CHIMES."—At the Centennial exhibition the chime bells exhibited by the McShane bell foundry, of Baltimore, is the only chime in the exhibition, and is composed of 13 bells, representing the 13 original States of the Union. These bells are all large, the smallest weighing about 300 pounds, and the largest upward of 4,000 pounds, the 13 aggregating over 21,000 pounds. They comprise a full octave and one third, with a flat seventh and a sharp fourth, and possess clearness, richness of tone and great volume of sound, and are constructed in the most admirable and substantial manner. The bells are hung in the main tower, on the northeast angle of machinery hall, near the main entrance (Belmont avenue) to the exhibition grounds. They are the first chime of bells ever cast in the State of Maryland. The bells are hung in a heavy oaken frame, with the largest of the 13 in the center, and are "played upon" by two rows of levers and one row of pedals, by means of steel wires and cast iron elbows attached to the bell hammers, rendering manipulation remarkably easy. The chime was cast expressly for exhibition at the Centennial, at a cost of over $10,000.

STRENGTH OF IRON AND STEEL PLATES.—Experiments have lately been made by the South Wales institute of mechanical engineers to show the durability of metals by percussive force. Plates of equal thickness in iron and steel were operated upon by gun-cotton. A three-eighth iron plate being placed on a cast iron block dished out, having a charge of three pounds of gun-cotton suspended and fired just above it. In the experiment on the iron plate the percussive force could not be resisted, the plate being entirely blown through, and though dished in the center, or depressed to a segment of a circle four inches deep, the dish was blown out of the plate and was otherwise much torn and fractured. But in the case of the steel plate under similar conditions the plate was depressed or dished to the full extent of the block, and left entirely uninjured and with a perfectly clean surface, thus demonstrating the superiority of steel over iron plates for boilers and other manufactures.

AMERICAN LUMBER FOR ENGLAND.—The *Northwestern Lumberman* says: The shipment of Michigan lumber to Europe is becoming quite popular this season. Mention has already been made of large purchases of deals for the Liverpool market, to be shipped from the mills by vessel via the lakes, Welland canal and the St. Lawrence. It now transpires that a new route is to be opened up, whereby the first stage of the distance is to be made by rail. Parties have been negotiating during the week past with mill men on the east shore of Lake Michigan for first, second and third quality stuff, to be shipped by rail to Jersey City, N.J., and thence re-shipped by vessel to England. A White Lake (Mich.) firm are already loading cars under contract with the parties who have opened the new route. Only the extremely low rate of rail transportation could admit of such a course.

THE FASTEST CABLE TELEGRAPHY.—On a recent occasion, when all the Atlantic cables were interrupted except the Direct, the entire business for two days was done on this one wire, and the average speed maintained for 48 successive hours was 10½ words per minute, and the highest speed attained was 18 words per minute. Length of cable, 2,500 nautical miles. This is the fastest ocean telegraphy ever executed on a cable of equal length.

AN EASY RAILWAY CAR.—The new railway car of the French engineer, Giffard, is entirely free from oscillating motion, being entirely separated from the truck, and suspended from the springs by universal joints. With all this, the weight is only one-tenth more than that of an ordinary car.

ROTARY SAWS were first used in Holland, where they seem to have been known during the seventeenth century, a period when the Netherlands had placed themselves in advance of every other country in many branches of mechanic art.

SCIENTIFIC PROGRESS.

Apparatus for Demonstrating the Transformation of Force.

In a recent number of the *Journal de Physique*, M. Crova describes a convenient apparatus for showing the relations between heat, electricity, and mechanical force. The arrangement is as follows:

Two of Clamond's thermo-electric generators are connected in surface, and put in communication with a Gramme machine in such a way as to set this in action. In the circuit is inserted a sort of electric lamp, in which a platinum wire placed in the center of a small globe (which protects it from agitation of the air) can be raised to incandescence. The only difficulty of the experiment consists in so regulating the length and diameter of the platinum wire as that it may be raised to a red heat, while the thermo-electric current retains sufficient intensity to drive the Gramme machine. A circuit entirely metallic then is obtained, with which the following transformations can be effected:

1. The Gramme machine being excluded from the circuit, a portion of heat, transformed into electricity by the thermo-electric pile, reappears in the state of heat in the platinum wire.

2. The platinum wire being excluded from the circuit, and the Gramme machine introduced, a portion of heat, transformed into electricity in the pile, produces mechanical work in the machine, which acts as a motor.

3. The platinum wire and the machine being included in the circuit, a part of heat, transformed in the pile into electricity, produces heat in the wire and work in the motor. If we then stop the motion of the Gramme machine, we find the incandescence of the platinum wire increased. The machine being liberated, on the other hand, is set a-going again, and the incandescence of the platinum wire diminishes in proportion as the motion is accelerated. In this way is rendered sensible to the eye the expenditure of heat necessary to develop an increasing quantity of mechanical work.

4. Taking the handle of the machine, we turn it in the direction of the rotation the current produces, but with an increasing velocity. In this way a velocity is reached such that the incandescence of the wire completely disappears.

5. If the handle be turned in a direction opposite to that of the rotation the current communicates, there is considerable resistance, and the incandescence of the wire increases rapidly; on turning more quickly, the wire is fused. Thus, in the metallic circuit under consideration, the circulation of a given quantity of energy may appear exteriorly in the form of heat or of mechanical work, the one of these quantities being the complement of the other. If by an exterior force we introduce into the circuit an additional quantity of work, the increase of the quantity of energy put in circulation is rendered visible by the incandescence of the wire; any communication outwards from the circuit, of a certain quantity of energy which circulates in it, appears, on the other hand, in diminution, or even disappearance, of the incandescence.—*Nature.*

NEW TELEGRAPH APPARATUS.—A new apparatus, says *Iron*, for telegraphic signalling, has lately been brought before the Society of Arts. It is the invention of a Spanish gentleman, and its object is to provide a simple and inexpensive system by which any number of stations, houses, fire offices, police-stations, etc., may be able to communicate with a central station by the same wire, yet without interfering with one another. With any system of telegraphy now in use this cannot be done. The essence of the new system may be said to consist of the use of two independent wires, the earth being in each case used to complete the circuit. Of these one wire serves to carry the message, the other to set the instruments and connections in a condition to carry it. Any number of persons can telegraph simultaneously, and their messages are received at the central office in the order of their position, those nearest the office being taken first. The signals transmitted are capable of considerable variety, according to the complexity of the instrument. They are given by the movement of a pointer hand on a dial. The signals required are marked on the dial face; and on the hand being brought to any given signal, that signal, with the number indicating the house, is recorded at the central office. The receipt of the message is shown by the return of the hand to the zero point. The principal signals suggested are for giving an alarm of fire, summoning the police, or desiring the attendance of a doctor. Street stations might also be arranged, from which a fireman or a police constable might communicate with the central office.

ORIGIN OF PETROLEUM.—We learn from the Philadelphia *North American* that "eminent philosophers" have come to the conclusion that petroleum is a cod-fish product. We quote as follows: These fish were once plenty in the ocean which covered the place where Pennsylvania now is. They were caught by a sudden avalanche of land, and the millions of decaying codfish caused the petroleum oil. This accounts for the salt water found in oil wells, being the result of salt cod-fish. It also accounts for the resemblance of petroleum to cod liver oil, and the number of fish stories told of immense fortunes which were never realized.

How the Toughened Glass is Made.

We have formerly made note of the Bastie toughened glass. It now appears that the manufactura has fairly begun in this country, and our readers will be pleased to know tha process by which the glass is toughened. The *Iron World* has examined the works at Bellaire, Ohio, and we extract the in ormation on the method of toughening. The article manufactured is a lamp chimney.

The chimney is taken from the blower and heated to dull redness in a small furnace of peculiar construction. This furnace is heated with benzine and its proper construction proved a serious difficulty for a long time. Four men are engaged in holding the chimneys in the flame of this furnace, the proper and equal heating of the chimneys being the most delicate part of the process. Benzine is used to avoid the deposition of carbon or soot upon the surface of the glass, otherwise the oil bath would permanently fix the carbon in the glass and ruin it. The oil bath consists of three parts of linseed oil and one of tallow, and is heated at 360 deg. Fahr. The heat derived from the chimneys may, by rapid working, run it up to 400 deg., beyond which it is not wise to go. A test while present showed 390 deg. The temperature of this bath is a thing to be watched. It is contained in a rectangular iron tank of 5 bbls. capacity. Over this tank is a sheet iron hood in shape like the roof of a house and in each side of the roof is an opening for the admission of the chimneys. The gable end of the tank is set against the furnace. To each furnace there are two such tanks, into which the workmen put the chimneys as fast as heated. In each tank two iron baskets with perforated bottoms are placed. When one is filled an empty one takes its place, and after sufficient time (from 10 to 16 minutes) has passed to allow the last chimneys placed in the basket to get the full benefit of the bath, it is lifted out and immediately plunged into a cold water bath. Out of this water bath the chimneys are taken as soon as possible and put into a tank of benzine to free them of oil. They are then taken out, dried, rubbed with bran and are ready to ship. A chimney can be blown and got ready for market in 30 minutes. It takes no ordinary blow to break them. They may be thrown to the ceiling of a room of ordinary hight and allowed to fall upon a bare floor without breaking, though it is our opinion that repeated shocks induce a condition that renders them as easily broken as any glass.

HOW FRENCH COLORS ARE PRODUCED IN GLASS.—In the *Bulletin de la Societie d'Encouragement* M. Baccarat describes the mode by which the far-famed French rose and red shades of glass are produced—one of the most critical and beautiful of the arts of industry. In brief, a certain amount of auriferous glass is prepared beforehand and run in thin plates, and fragments of these plates are used by the glass blower to fuse upon his work, and thus give it a superficial coloration. It often happens that one and the same composition of auriferous crystal gives plates of very different shades—some colorless, others tinged more or less deeply with rose and red, and some almost black; these differences being due to two causes—namely, the temperature of the furnace in which the fusion has been effected and the temperature of the mold into which the melted metal is run. For light colored plates the temperature of the furnace is made low and the mold very cold. Blue plates are sometimes produced under the same circumstances, which, if reheated, take the normal color; as do also the colorless and very pale rose glasses. The curious facts thus developed in regard to the process in question and its results render it probable that the coloring matter is neither a salt nor an oxide, but a simple body. Crystal colored with gold is, therefore, merely a vitreous matter, holding in suspension a metallic gold in a state of very fine subdivision. It is stated that, on attentively examining the red plates, it is easy to recognize in the mass a multitude of most brilliant specks of metallic gold, forming a sort of adventurine.

MEASURING DISTANCE BY SOUND.—The old method of measuring the depth of a well or shaft by the time a stone is heard to reach the bottom, may be improved upon by taking into account the time required for the sound to reach the ear from the bottom of the shaft, a correction only of any consequence when the shaft is very deep, as half a second is all the time required for the sound to pass over a distance of nearly 550 feet. If we could appreciate small fractions of seconds, it would become possible to determine distances by sound with great accuracy. This is what has been accomplished by Major Le Boulanger of the Belgian artillery; on seeing the flash or smoke of a gun, he touches one key of an instrument, and the moment the sound is heard, the other key is touched; in the mean time the clockwork of the instrument has been set going by touching the first key, while it has been stopped by the second key, and the space passed over given the time within one-twentieth of a second, which corresponds to an accuracy to within 50 feet. The advantage of this in artillery, especially for coast defence against an attacking fleet, is expected to be very great, as it will enable the gunners to make the determination of the distance of a hostile ship the work of a moment—a problem thus far difficult and doubtful of solution, and of the utmost importance in regard to a successful defence.—*Builder.*

The Mining Share Market.

The stock merket hae been of late so peculiar end so sensitive to the eligh teet preeeure, that operetore heve been ntterly at a loss, end the prophets who ere so numerous ehout the hoard rooms heve found their gift deceptive and themeelvee completely at eea. Mining sharee heve in the pest few weeke fluctnated in a most etartling manner. It is sefe to eay that there are few, not even excepting the ineide manipulatore, who have not been caught in some nue of the sherp turns which have been so common. The market hae, however, been grednelly hecoming more and more eteady, end the close of the week under review showe it to be again in a healthy condition. Prices are now low, compared with those ettained during the epring months, but the panicky feeling which prevailed a short time ago seeme to have altogether disappeared, and the market stands at last on a freeh and apparently sound baeis. A large unmber of persone, principally those who do not make a prectice of habitually dealiug in etocks, are elways induced in eeesone like the present to take in a supply of sharee for the winter market. This gives rise to a elow and steady npward movement, until it becomes evident that the managers of the market are not ready for a riee and that the strength is the reenlt of outeide purchases. Thns it is a common thing to note e falee ertert in summer. However, for the present the market ie well snsteiued and shows no signs of e eerions relepse—at least for the present. The wreoks of the late penio ore oleared awey end the majority of unsound accounts eliminated.

How to Use a Grindstone.—1et. Don't waete the etoue hy ruuning it iu weter, nor allow it to stand in water when uot iu use, as this will cause a eoft place. 2d. Wet the stnue hy dropping water on it from a pot snspended above the etone, and stop off the weter when not in nee. 3d. Don't allow the stone to get ont of order, but keep it perfectly round by the nse of a piece of gae pipe or a hacker, or use e peir of the double hung etones, which keep eech uther in order. 4th. Clean off all greasy tools before sharpening, es grease or oil destroys the grit. 5th. Observe—When you get a stone thet euits your purpoee, send a sample of the grit to the dealer to eelect by; half an ounce sample ie enough, and oeu he sent in a letter by mail.—*Iron Age.*

The Senete hae paeeed the bill for the completion of the Weshington mouument. It approprietee $100,000 to coutinne the work after the Waehiugton eociety shall treuefer to the United Statee all its rights and privilegee, and providee that the work shall he under the direction of the President of the United States, the Snpervising Architeot of the Treasury and the Architeot of the Cepitol.

A Washington epecial to a Chicago peper thinks Secretary Robeson will escepe impeachment. Nothing will be done in the matter heyond preeenting the evidence to the Houee and having it referred to the Judiciery Committee to report next eession.

The emonnt in the River and Harbor bill for the improvement of Sacramento and Feather rivers is $15,000, not $75,000.

The weather has moderated greatly in New York, end the deeth rate hee correspoudingly deoreased.

With a cake of Glenn's Sulphur Soap and e oom modious beth-tub, the victim of chronic cutaneous eruptions can improvise a sulphur bath, which no professed bathing establishment can supply. Give it a trial. It is sold everywhere.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

Will Start Up.—Alpine *Chronicle*, July 6: Work on the I X L mine, near this town, will be resumed on Monday next after a rest of about two years. The new foreman, Mr. Ferguson, arrived last evening from Grass Valley.

Bonded.—We learn that the Rippon mine, now called the Occident, has been bonded to an English company who propose purchasing it within three months for $50 000.

New Pump.—This week a powerful pump was sent up to the I X L mine, work upon which will be resumed next week.

Brick.—Brick making for the new furnace at the Exchequer mill has commenced.

Hauling Ore.—Ore is being hauled from the Exchequer mine to the mill.

Inspecting.—Messrs. Williamson, Hendrickson, Folger, Rice and others are engaged this afternoon in inspecting the tunnel and works of the Mountain mine, work upon which will shortly be resumed, after a resting spell of about eight years.

AMADOR.

Phenix Mine.—Amador *Ledger*, July 22: The additional 20 stamps which have been put in the Phenix mill will be started some time next week. The mill will then be equal to crushing 120 tons per day—about two tons to each stamp. The ore body in the mine is so vast that there is a report to the effect that 20 more stamps will be added at no remote date, making the mill 80 stamps—the largest in the county.

BUTTE.

Heavy Gold Shipments.—Oroville *Mercury*, July 21: Last Sunday morning Wells, Fargo & Co.'s express took from their office in this town a little over $130,000 worth of gold dust and bars, to be shipped to the mint for coinage. Lest our readers may suppose that it has taken some time to get in this large amount, we will further add that within the last ten days almost a quarter of a million of dollars' worth of dust and bars have been shipped. These figures we get from the express office, and they are correct. They only serve to show that more gold is being taken out the present year in this part of the State than ever before. They explain, too, the reason that while all the rest of the State is suffering greatly for the want of money, the people in this part of it have some money by them all of the time. All this gold comes back in coin, or rather a great part of it, and passes into circulation. Every man that works for a company gets his pay regularly.

CALAVERAS.

Quartz Mining Items.—Calaveras *Chronicle*, July 22: At the Gwin the sinking for the 1200-ft level is completed with the exception of the sump. It will be finished up entirely by the first of August. The batteries are still kept employed on rock from the 1100-ft stopes, the yield continuing fully as good as heretofore. The idea of sinking the middle shaft has been abandoned, and it is contemplated to run a level north, at the depth of 1200 feet, with a view to prospecting for a chute of ore in that direction. The new machinery at the lower or Alexander mill is not yet completed. Very encouraging developments are being made in the Quaker City mine, at the Junction. A compact vein of fair milling ore, five feet and a half wide, has been uncovered. A level is now being run at the depth of 200 feet, to determine the length and extent of the ore body. The level is being driven through the gangue, parallel with the ledge, the vein itself being so compact and hard that but little progress could be made in it. The lode will be prospected by cross-cutting from the level as work progresses. The outlook for the mine is altogether favorable. At the Lamphear mine the work of putting in a pump is being urged forward as fast as practicable. All the new machinery is now upon the ground, and it is expected to have it in position and ready for running next Wednesday. As soon as the pump is in and the mine freed of water, sinking will be commenced, the intention being to put the shaft down 100 feet deeper. Its present depth is about 100 feet. The company that recently purchased the Mount Tmolus mine, Jesus Maria district, have commenced work. A contract has been let for putting the shaft down 50 feet deeper, labor upon which is being prosecuted. The purchasers of the mine mean "business" and have abundant funds to conduct operations upon as extensive a scale as they choose. There is not a more promising piece of mining property in the county than the Mount Tmolus.

Upper Country Mining Splinters.—The chute of pay ore recently discovered in the Mina Rica, at West Point, is developing splendidly. The ledge is about 15 inches wide, very rich and increasing in size. It is thought to be a continuation of the ore body discovered and worked in the mine several years since, trace of which was lost. Rock of extraordinary richness continues to be taken from the Champion. The mine is looking better than ever, and it has proved itself to be one of the best in the county. Reports from the Josephine continue favorable. The mill being erected on the mine will be ready to run about the first of August. Williams & Chick have lately discovered a promising vein of quartz in Soaproot gulch, near West Point. Garland's mill, at Mosquito, is employed crushing rock from Sundermier & Co.'s mine. 300 tons of ore are on the dumps of the mine owned by Drs. Clark & Langdon, of Stockton. The mine is located near Albers' ranch, a short distance from Mosquito. They have contracted for hauling the rock to Garland's mill.

Rich Strike.—*Mountain Democrat*, July 22: Wm. P. Nichols has made a rich strike in the northern extension of the Naper mine, Poverty Point, near this city. Mr. Nichols has been patiently prospecting this claim most of the time for three years. Single handed he ran a tunnel about 35 feet, when he struck the ledge. Then he drifted south 30 feet, but failed to discover any paying ore. Then he drifted north 30 feet, when he struck a fine deposit of excellent rock, from which he has been extracting good pay for about 10 days, and the quality and quantity constantly improving. Another instance of industry and perseverance rewarded! It is well.

INYO.

Lee District.—From Mr. Peter Taylor, superintendent of the Emigrant company's mines, at Lee district, who came in last Wednesday, we learn the following: The Cactus mine is opening up beyond all expectations, both as regards quantity and quality of the ore. The main ore channel, as far as is shown by sinking and cross-cuts run, is fully 22 feet wide, all fine milling ore that will pulp from $80 to $100 per ton. On the foot wall a fine clay selvage of three inches has been found, showing beyond a doubt the true fissure character of the vein. A new shaft, started one week ago on the Cactus, is now down seven feet, and is all the way through a splendid body of ore, its width at the bottom not determined, but it is thought it will, when cross-cut, be not less than 20 feet in width. The ore in this shaft is of the very finest character, and of higher grade than that found in any other part of the mine. On the Valentine a new shaft has been sunk between the old openings heretofore reported, and is now down 30 feet, and discloses a fine body of rich chloride ore, interspersed with free gold. The vein at this depth is fully four feet in width. The ore will pain at least, as shown by assays taken, $250 to $260 per ton. The mill has been running some 10 days altogether, and of course experienced the difficulties attendant upon new machinery, but yet, although running upon the lowest grade ore to be had from the mine, has turned out six bars of very fine bullion, valued at $6,500. Mr. Taylor thinks he will be able to reduce six to eight tons per day. It must be understood that these ores are free milling, and no trouble whatever is found in working them up to 80 per cent. of their assay value.

LAKE.

Valuable Discovery.—Lake County *Democrat*, July 22: Wm. Barton, of Lower Lake, has recently discovered a very valuable quicksilver mine, on old Konokti, adjoining the Uncle Sam, of which it is an extension. It is being thoroughly prospected, and already gives indications of the development of as rich a mine as the Uncle Sam.

Another Mine.—About a mile due west of Thurston lake, between that lake and the Uncle Sam mine, H. B. Callahan has just discovered a very rich ledge of cinnabar, which can be traced for 3,000 feet. It is located by Messrs. Callahan, Crigler, Snow, Bertou, Adams, Whits and Marshall, and work will be commenced on it on Monday next.

New Furnace.—Napa *Reporter*, July 22: Two new furnaces are nearly ready for firing up at the Sulphur Banks quicksilver mining company's works, in Lake county, either of which will yield, according to estimate, 16 flasks daily, or 960 flasks monthly. This will make the current monthly yield of the works, when the new furnaces are set agoing, nearly 2,000 flasks monthly. Other new furnaces are to be erected, until 3,000 flasks per month are turned out.

NEVADA.

Greenhorn.—*Foothill Tidings*, July 22: The Greenhorn mine, which was abandoned some time ago and the machinery taken away, has lately been worked upon with such success as to develop a good looking ledge four feet thick.

Fire at the Pittsburg mine—the old Whigham—near Nevada City, on Monday night last, destroyed the hoisting and pumping works. Loss estimated at $30,000. Supposed to be incendiary work.

A tunnel under Osborne hill would be a good work and it is believed a paying property. We hope the talk now heard about such a tunnel will result in some systematic plan of operations which shall be carried out by actual work.

Ledge Cut.—We understand that Mr. Berry, who has been driving a tunnel in down below Allison ranch, between there and Forest springs, cut into and through a fine 3-ft ledge, on Thursday afternoon of this week. We will try and give more particulars next week.

Omaha.—This mine is now sending up splendid quartz—sometimes pieces which contain more gold than quartz—and she will be up at to give a good account of herself this month, as the 18 stamps are at work regularly. We hear the most flattering reports about this valuable mine.

Yuba.—This company are putting up some fine improvements at their mine above Washington, consisting of a new overshot water wheel—36 feet in diameter and six foot breast—two new mortars, with rubbers and pans for the mills. The mine is looking, we are told, as well as ever.

Franklin Allison.—The shaft on this mine is still going down and the ground getting harder. Drifting on the ledge above continues, and the quartz taken out looks fine, showing gold and sulphurets. The dirt around the ledge is said to turn out from 25 cents to $1 to the pan.

On the South Yuba, in the vicinity of the Yuba mine, there are several claims which give promise of excellency soon. The Linsey has lately resumed operations and, if properly managed, ought very soon to enter upon the list of paying properties. The Canyon Creek mine has changed hands and started up under quite favorable auspices. The Last Chance, which has given indications from the croppings of a rich ledge, is being opened up by tunnel, Mr. J. F. Smith having the contract. Mr. Jones, former owner of the Yuba, is the owner of the Last Chance.

PLACER.

Mining Items.—Dutch Flat *Forum*, July 20: Since our last issue there has been but little change. The various claims then washing have continued without interruption, excepting the Elmore Hill claim, which is idle, pending some repairs to the derrick, which will take four or five days. The derrick has become such a necessity that the superintendent of this property preferred to suspend washing rather than attempt to run without it. The Yankee has resumed washing again, but is using water only about six hours per day, the balance of the 12 hours being devoted to the removal of the surface rocks, of which this claim can produce more than any piece of mining ground of the same size in the State of California. The gravel, however, is rich, and were it not for the immense slide above, this claim would produce a wheelbarrow load of the precious metal every month. The Polar Star continues washing and is removing the hank very fast considering the character of the gravel. This claim cleaned up on Tuesday after a short run. From the quantity of amalgam we saw the superintendent cleaning yesterday we should conclude that the result was satisfactory. The Franklin, Boston, Snmmersett, Pacific, Central and Dunning claims continue washing.

Water Ditches.—Our water ditches hold up well. As we write they are conveying nearly a full head of water. It is expected, however, that in a day or two the Yuba will be so low that the Miner's ditch will be dry.

The Yankee tunnel is being driven with vigor. During the week ending last Saturday night, the tunnelers fired nine face shots and advanced 38 feet, being an average of 4.22 feet per shot.

SAN BENITO.

Antimony and Quicksilver.—Santa Cruz *Courier* July 21: The tunnel of the Salinas quicksilver mine has been carried in 125 feet, and a solid vein of antimony, 12 inches thick, has been struck. Veins of quicksilver run through the antimony and all over the face of the tunnel.

SAN DIEGO.

Banner District.—San Diego *Union*, July 20: Nearly all the mines are being actively worked. The people are all busy, and a cheerful feeling prevails. We may mention the mines now being worked as follows: The Medden mine, owned by Joseph Coyne and Murray, and leased by Messrs. Cooper, Clyde, Ellis and Smith, has just had a clean-up, averaging $65 to the ton. The Hidden Treasure, run by Brittain and Woods, has just cleaned up $90 per ton. Messrs. Bailey and Bralley, on the Kentuck, have lately had a crushing, and have cleaned up $50 per ton. The Hubbard mine has made a good showing. It is being worked by Messrs. Woodruff, Allen, Jones and Woods. They have recently had a clean-up, the ore running $35 per ton. The sterling old Ready Relief mine is now leased by Messrs. Shoup, King, McDowell and Edmunds, who will work it during the absence of Mr. Neyhart in the East. The last clean-up of this mine, just before the Fourth, averaged $35 per ton. At the El Dorado mine, Messrs. Murray, Atkinson and Robinson have lately had a crushing, averaging $50 per ton. This mine is owned by Mr. Courtney. It is regarded as an excellent property. Messrs. Pontney and Thomas Jones have discovered a new ledge, which has been patriotically named "76." They have taken out ore which runs upwards of $100 to the ton. Since January 1st there have been constantly employed in Banner district about 35 men, and they have taken out over $31,000. The average has been $120 per month to the man. This is certainly a good showing for our mines.

SIERRA.

Scales' Diggings.—Cor. *Mountain Messenger*, July 22: The water season this year was not much longer than usual, owing to the almost unprecedented heavy snow fall, causing the miners to lose over two months working time. All the diggings here, however, have yielded good returns. Boyce Bros. claims have paid exceedingly well this year. The gold could be seen in numberless places sticking out of the gravel. They have been rapidly opening the main channel, and the prospect for a rich harvest the next season is very promising. At the last clean-up of the Williams claims, the owners were happily surprised on penning out five instead of three thousand dollars, as was first anticipated. Williams and McChesney have gone below with their dust. No work is being done now at Poverty hill except on the Main tunnel company's tunnel (where two feet has been made during the past year) and some repairs in the mines.

Sierra City.—I believe that, as there are even now several claims which are worked with good advantage, there are undoubtedly others that well only for the searching picks of industrious prospectors to yield up to us again their hidden treasures. Without having any pretensions to being an expert in these matters, my opinion is, that miners in general are very easily discouraged, as they are easily excited, and having seen so many claims play out, they have lost faith in them, and either leave the diggings or don't work at prospecting with the will and perseverance they once had; but let us hope some big bonanze will yet be struck around our hills to relieve us from this lethargic condition.

SISKIYOU.

Mining Again.—Yreka *Union*, July 22: Mining has commenced again in the deep claims on McAdams creek, most of the claims having been to work for a couple of weeks. The miners were considerably later getting into the claims this year, on account of their being flooded with water last winter, and it took a long time to get the mines clear again. These claims paid very well last year, and there is no reason to doubt that they will do equally as well this year.

Prospecting.—We learn that a great many prospectors have fitted out at Sawyer's bar this summer, and gone prospecting for quartz and placer mines in the Salmon section. The mountains around there are almost alive with prospectors, and it will be something remarkable if some good mines are not found there this season. That section of the county is a fine field for prospectors—in fact, we know of no better.

SHASTA.

McCloud River Mines.—Cor. Shasta *Courier*, July 22: The McCloud river mines are attracting more and more attention daily. A considerable number of men are engaged prospecting the different ledges, and new ledges that have a fine appearance are being continually discovered. I understand that some parties have now gone to purchase a quartz mill, and will proceed to erect the same immediately in the neighborhood of Bivens' ledge, so as to thoroughly test the rock.

TUOLUMNE.

Mining Enterprise.—Tuolumne *Independent*, July 22: A mining expert, Mr. H. H Folinghy, of San Francisco, is here who is projecting a gigantic mining enterprise which, should his plans be matured and the theory which he advances prove correct, will create a new era in the mining interests of this county. He proposes through a system of shafts or inclines, or by tunneling, to develop what he terms an underground channel (subterranean river) which is believed flows in a southwesterly direction through the county. His theory is not new, as the same ideas were advanced years ago by scientific and practical miners who had become familiar with the geological formations embraced within the limits of what originally formed the several mining districts within the county. However, so far as our knowledge of what has been done in this respect towards proving the correctness of the theory, he is the first to have made an actual commencement in a practicable manner to demonstrate if or the fact of this much talked of underground channel existing. Mr. Folinghy has commenced sinking a shaft in Main gulch, on what was formerly known as the Cascade claim.

PLUMAS.

Ledge Found.—Plumas *National*, July 22: A short time ago two Spaniards found a streak of quartz crossing the road from Greenville to Round valley. The streak was about six inches thick, and they have run a tunnel into the hill about 30 feet and the ledge has "widened out" to about two feet. Ten tons of the rock was crushed, and yielded $57.50. This looks as though they had something which will develop into a valuable mine. That mountain seems to be a perfect network of rich quartz ledges.

Another Mining Venture.—We learn that O'Toole, Lathrop and some others have commenced operations and will put up machinery to develop the deep channel which is known to exist in the main canyon above Elizabethtown. It is the opinion of many old miners that this is the one that fed or furnished the Elizabethtown mines with their riches, and as long ago as 1856 an effort was made to open it. The tunnel run by the company was a long one, and was found to be too high. Several shafts were sunk from the tunnel, but each had to be abandoned before bedrock was reached, on account of too much water. One shaft got down into big boulders, and it was reported that a good prospect was obtained at the bottom. The present owners propose to sink to the bedrock by the aid of steam pumps and thoroughly prospect the channel. If they strike diggings a tunnel will be run to drain the ground. We believe this operation will be a successful one, and hope to see the new company strike it rich.

Change for Miners.—We heard an old miner talking about the country around Long valley the other day, and he expressed the opinion "that there were more good gravel mines in that range than would be worked out in the next 100 years." The same may be said of all parts of Plumas, and from the number of prospectors coming in, and the new locations that are being made, we should judge that the outside world was beginning to find it out.

Mine Sold.—We learn that Messrs. Green & Brewster, of San Francisco, have purchased the Gold Stripe quartz mine, on Wolf creek, of Mr. Augus McIntyre. The price paid was said to be a good one, but we have no figures. It is rumored that the new owners will put up a 40-stamp mill as soon as they can get the mine opened properly.

Big Chunk.—Not long ago, a Frenchman called "Big Larry" found a piece of quartz and gold in French ravine, a short distance below the Rich Bar quartz company's ledge, which weighed 64 pounds, and which was fairly "lousy" with gold. He refuses to have it broken up, and it is hard to tell how much it is worth, but it certainly is very valuable. We shall be glad when the company spoken of above get to work again. There is but little question that a little capital and well directed labor invested there would open a mine of fabulous wealth.

Nevada.

CORNUCOPIA DISTRICT.

The Mines.—Cor. Oakland *Transcript*, July 20: Most of our mining companies here are organized in San Francisco, or in your place, and sometimes great inconvenience is experienced by our different classes of business men, on account of the irregularity of pay days. All the money we get here is from the product of the bullion taken from the mines—and from the foreign corporations which are prospecting here. I hope no Oakland corporation will miss their regular pay day. That the mines in this vicinity are of inestimable value you would not doubt a moment could you once examine them. The Leopard is now shipping bullion regularly, and they are putting on more men every day. Their mill is in full blast, reducing about 25 tons per day, and although they are now working second grade ore, the bullion receipts come up to expectations. The Hussey, Panther and Alameda are working steadily. Of the latter I cannot say as much as I wish I could on account of the absence of Mr. Harry Harville, the superintendent, who is now in Elko on business—I suppose in connection with the mine—but from all that I can learn they will eventually have a good mine on their location. They are now down about 67 feet, are troubled with some water, but not enough to impede work. Everything indicates that they are in the right spot and will ultimately have another Leopard bonanza. There are undoubtedly many good claims on the same range, which are not yet developed at all, but will probably be this season.

ELY DISTRICT.

Furnace Meeting.—Pioche *Record*, July 18: The subscribers to the furnace enterprise met on the 17th inst. Mr. Bishop, in speaking of the resources of the camp, said: That this camp has placed in the arteries of commerce $60,000,000; spoke of the Raymond & Ely, Meadow Valley, Huhn & Hunt, Washington & Creole, Desdemona, Ward Beecher, Chief of the Hill, Havana, Ely mine, Chisholm, Clinton, Fer West, Highland mines, Bristol mines, Blind Mountain mines, as all producing plenty of bass ore and it became the duty of all business men as such and as financiers to build a furnace and give employment to 150 to 200 men, also to numerous men to develop and extract base ore. Mr. Bishop continued by showing that all mining camps had dull periods, and Pioche could not expect to be any exception; that until the Raymond & Ely and Meadow Valley were able to work below the water level the camp could not expect to see any better times; in the meantime people would starve if they did not stir in some way. Business as a whole was inclined to be stagnant. He stated that a responsible individual had agreed to build a furnace and put it in order to commence to run, for $5,000. That charcoal could be furnished for five cents a bushel, cheaper than what it was now sold at. He called on every one to subscribe, even if they could subscribe no more than $5. Mr. Bishop stated that he had started in on this business and was determined to see it through if he had to interview every individual in the town. He called on all to come up and subscribe at once.

EUREKA DISTRICT.

Rumors About the Richmond.—Eureka *Sentinel*, July 15: There are some pretty well authenticated rumors afloat to the effect that the Richmond company will suspend operations on the first of the coming month. Both the mine and the reduction works are to be closed down for an indefinite period. The great decline in silver is assigned as the reason for this step. How long work is to be suspended must, of course, depend wholly upon circumstances. We hear among other things that the management was inclined to continue in active operation provided all of the men in the employ of the company would stand a reduction of 50 cents a day each on their wages. Such a proposition, however, was not made to the men, for the simple reason that it was feared they would not accept the terms. In the meantime it is mooted by the head officers of the company that they expect that after the works shall have been closed down for a time the men will readily consent of their own accord to work for reduced wages, possibly $3 per day. At all events, it is asserted by those who should know that the Richmond, when once closed down, will not again resume until there is an advance in silver or a reduction of wages. There has been some talk among the managers of the company about attempting to secure a reduction of wages while the present low figures for silver shall rule, with the understanding that the price of labor should be advanced to the old rates whenever the silver market would warrant the change. It is hardly probable, however, that such an arrangement could be effected with the miners, for the simple reason that they well understand the difficulty of getting wages advanced when once they shall have been cut down. The determination of the Richmond to close down gives our town a bad name in a money aspect, for this company has given employment to a greater number of men during the last few months than all the others combined. We can see nothing but a dull season ahead of Eureka; not because our mines are not as good as ever before, but for the reason that silver is at such an enormous discount in the markets of the world. The most that can be hoped is for an early advance in silver to such a standard as will permit the working of our mines as in the past.

REESE RIVER DISTRICT.

Landen Hill Mines.—*Reese River Reveille*, July 22: Aside from the extensive and valuable mining properties of the Manhattan company, there are other companies working mines on Lauder hill, which are beginning to loom into importance. The Pacific mining company (limited) have now two shifts of men employed in prospecting the lower levels and in extracting ore, and developments are favorable to the employment of a largely increased force at an early day. The King Alfred company have completed their shaft to a depth of 300 feet, and will shortly commence the opening and development of their ledges, of which quite a number were cut by the shaft while it was being sunk. The mining outlook for this district was never so bright and encouraging as at present—barring the drawback of the discount on silver—and there are many reasons to hope that this will shortly be overcome, and that Austin will, before another year has passed, take rank among the largest silver producing districts in the State. We hardly like to say how rich and extensive we think the mines of Lander hill are destined to be, because so many erroneous reports have been circulated about the amount of silver to be produced by Nevada to have an injurious effect on the price of that metal, and the *Reveille* don't aim to influence the silver market for the worse—and if we should tell just how rich our mines are it might create a panic in the London silver market. Results speak louder than words, and if our mining industry should not be too seriously interfered with by a low price for silver, ere another year shall have passed the world will learn from results that the mines of this district are among the richest and most permanent on the globe.

WASHOE DISTRICT.

Savage.—Gold Hill *News*, July 20: The new pumping engine is in place. The pipes are all fitted ready to turn on steam. A portion of the pumps have already been placed in position in the shaft ready for use, and the placing of the others is going ahead at a very favorable rate of progress.

Sierra Nevada.—A new station is being opened at the 1750-ft level for the purpose of commencing the prospecting of the ledge at that point. On the 1500, 1250 and 1000-ft levels the prospecting drifts are being pressed ahead at all points.

Crown Point.—The south drift on the 1700-ft level has penetrated to within a very short distance of the Belcher line without developing anything of value. On the 1600-ft level the east prospecting drift is still pushed vigorously forward.

Dayton.—The flow of water at the bottom of the shaft has considerably retarded the progress of the sinking.

It seems to he again gradually decreasing in quantity.

HALE & NORCROSS.—Taking out tha old pumps and enlarging the stations, preparatory to putting in the new, is going rapidly forward.

WARD.—The south drift in tha Julia is gaiting well advanced toward the Ward line, tha face of tha drift being still in quartz and ore of a very favorable character.

KENT.—Sinking the main shaft is making good headway.

CON. VIRGINIA.—Sinking the shaft to the 1550-ft level is being pressed ahead with all possible vigor. The use of the shaft for tha purpose greatly interferes with the extraction of ore and the work in the other portions of the mina. It will take several days yet to completa the work and put the shaft in good hoisting condition. In the meantime the delay in extracting ore has been taken advantage of to advance all the proapecting drifts heretofore stopped in the southern portion of the mine, and thus prospect and complete tha ventilation of that entire section. On the 1700-ft level the north drift from tha Best & Belcher has reached a point opposite the south winza sunk below the 1550-ft level, and a side drift has been started to connect with the bottom of the winza for ventilation purposes. The drift is fearfully hot and can make but slow progress. The new cylinder head was placed on the engina at the C. & C. shaft yesterday, and an initial cylinder added to make the engine a compound low pressure instead of a high pressure, as heretofore. In the meantime the water is being kept down by a constant use of the tanks. The shaft appears to be draining the entire surrounding country, having even dried up the water as far south as the Gould & Curry shaft.

CALIFORNIA.—Daily yield, 700 tons of ore, keeping the mills running and crushing up to their full capacities. The ora bressts are both looking and yielding well. The mina is being gradually opened in the most systematic manner possible and promises a rich yield of good ore for many months to come; in fact it is hardly yet touched as regards the extraction of the ore bodies already thoroughly prospected and known to to exist down to the 1650-ft level. On the 1550-ft lavel an opening has just been made to commence the extraction of ora. The same is being done on the 1600-ft level. Above the 1400-ft level the enlargement of the winze in the ora body, extending up to the 1300-ft level, is showing the quality of tha ore body to ha of a much richer description than was ever expected that it would be. The entire loss of the C. & C. shaft for the past two weeks has worked a great disadvantage in the extraction of ore and the development of the lower levels of the mine. The erection of the new battery mill near the C. & C. shaft is steadily progressing.

JULIA.—The south drift on the 1600-ft level is making steady progress to the southward, tha faca of the drift showing some very fina quartz, tha ledge continuing to improva as the drift advances. During the first portion of the week cutting out for a pump station was commenced on the east side of the shaft at the 1700-ft leval. The workmen had only penetrated the ground a distance of about four feet when a fine body of quartz and ore waa struck. This body of quartz has been penetrated for a distance of 16 feet, and is one of the most encouraging developments yet made in the mine. It is entirely distinct and separate from all the quartz before found in the mine. It has a regular dip of about 45 degrees to the eastward, and tha quartz and ore is of the pure Comstock character. Highly encouraged by tha extent of the development on the 1700-ft level, Superintendent Thayer has started a drift east on the 1800-ft level to cut and prospect the ora vein in that direction.

OPHIR.—Daily yield, 280 tons of ore, keeping the mills all steadily running. The ore breasts show well on the 1600-ft lavel, both north and south. Driving the north drift on the 1600-ft level, toward the Mexican lina, is making favorable progress. Retimbering and preparing tha 1700-ft level for mora rapid prospecting operations is going steadily forward. Work on the main inclina is being pressed at three different points with a strong force of workmen. The mine is showing well at all points, and it will not take very long now to complete the main incline down to the 1700-ft levcl, ready to than take a naw dapartura, and ascertain what there is of vaiua at and below that point.

BULLION.—The upraise from the 1700-ft level and the winze halow the 1400-ft leval hava approached to within a very few feet of each other, last evening tha force of blast sat off in tha winze having driven the powder amoke through the interstices of the rock into the upraise halow, so that it cannot take a much greater laugth of time to complete the connection. Owing to a necessity for the use of all the air obtainabla on the 1700-ft level, the Alpha drift on the 2000-ft level has been discontinned for the time. It will be started up again just as soon as the air connection on the 1400-ft level is completed.

IMPERIAL CON.—Sinking the north winze below the 2000-ft level is going steadily forward, the bottom still in ore, though not of so rich a character as much of that already passed through in this winze. At the dapth of 100 feet halow the 2000-ft level a drift north has hean started. Thia drift is now in a distauce of 20 feet in favorable ground. It is being run west of the ore vein, and therefore does not touch the ore body in the bottom of the winze.

JUSTICE.—Daily yield, 70 tons of ore, keeping the Excelsior and Woodville mills running up to their full crushing capacities. Tha sherman mill has been obliged to shut down a few days for repairs, but will ba in good running condition in a day or two more, when it will resume orushing as before. Tha ore breasts between the 400 and 600-ft levals are showing splendidly.

YELLOW JACKET.—The north winze on tha 1940-ft level is down to tha 2040-ft level. A station has been completed at that point and a drift started to connect with the drift now being run from the east winze.

CHOLLAR-POTOSI.—Daily yield, 75 tons of ore. There is no change of interast in any of the ore breasts on the old upper levels of tha mine. The new and powerful hoisting engina is in place and will be ready to steam up in a very few days. The erection of the pumping machinery is going steadily forward.

AMAZON CON.—The combination shaft of the Amazon and Glasgow companies has now attained a depth of 356 feet. It is thoroughly timbered and is in excellent working condition to that point.

BELCHER.—Daily yield, 350 tons of ore. The erection of the new pumping machinary is being forwarded at a very rapid rate. The steam pipes are being connected with the powerful hoisting engines.

OVERMAN.—Sinking the shaft is making fair progress. The foundationa for the new pump are about completed.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline is going steadily forward. A strong flow of water has been encountered during the past two days, which is being kept under control by the pumps.

WEST BELCHER.—All of the prospecting drifts are being pushed ahead with all possible dispatch. The ore chutes on the 350-ft level will be in readinesa for tha reception of ore by to-morrow. As soon as these ore chutas are completed, it is the intention to commence hoisting ore from that portion of tha mine for milling. If nothing unexpected happens to prevent, milling tha ore will be commenced in a very few days.

MEXICAN.—The face of the north drift on tha 1465-ft level is again showing much better prospects of quartz and ore.

NORTH CON. VIRGINIA.—The mason work on the foundationa is completed, ready for the reception of the new machinery as fast as it arrives on the ground. The pump station and hob pit at the 900-ft level is about completed. The drain tunnel is steadily advancing eight feet per day.

HERALD.—The incline on the veln is down 55 feet, showing 18 inches of high grade ore—black sulphurets, chloride and native silver. Tha ledge is constantly improving in width and quality of ore.

SUPERIOR.—The flow of water at the bottom of tha shaft has been overcome and the sinking resumed in good earnest. The bottom is in soft ledge matter, carrying streaks of fina ore. The prospects of the mine are very encouraging. The new pumping machinery will be up ready to run in a very few days.

KOSSUTH.—The main south drift on the 350-ft level is being pressed vigorously ahead, the face in quartz and ore of better description than has been encountered for some time past.

PHIL SHERIDAN.—Sinking the shaft is going steadily forward. The flow of water at the bottom is at times quite strong.

EUROPA.—The face of tha north drift on the 500-ft level has passed into very hard blasting rock. The flow of water is steady.

NEW YORK.—Work haa been resumed in all parts of the mine in good earnest. We now confidently look forward to a steady, uninterrupted development of the mine.

EAST JUSTICE.—Gradiog for tha building and machinery has been commenced and will soon be completed.

NIAGARA.—Sinking the main incline is going ahead at a favorable rate. The bottom is still in soft ground, full of small veins of quartz and ore of a highly encouraging character.

SUCCOR.—A large force of workmen are employed in preparing for tha reception of the new pumping machinery.

ROCK ISLAND.—The flow of water is still strong at the 350-ft level. The drifts have been repaired and put in working order.

ALTA.—The erection of the naw machinery is going favorably ahead. It is confidently expected that everything will be in readinesa to start up by the first of August.

TAHOE.—Sinking the shaft is making good progress, the rock in the bottom being softer, with a slight seepage of water.

BROOKA.—The new machinery is expected on the ground during the coming week, and as soon as it arrives and can be set up work in the mine will be resumed.

CALEDONIA.—Tha pumps again have the water under control, and the sinking has been resumed.

OOULD & CURRY.—The repairs to the shaft are rapidly approaching completion.

PROSPECT.—Shaft down 400 feet. An opening for a station is being provided for at that point.

TWIN PEAKS.—By reason of tha large amount of grading being done for the surfaca works, sinking the new shaft is discontinued for a few days.

NEVADA.—Main drift cross-cutting the ledge in a westerly direction, with the face all in solid quartz, with streaks of good ore. Ledge shows wide at this point.

MITCHELL.—Winze making good downward progress, with the bottom in low grade ore. Prospects excellent.

SUTRO TUNNEL.—Face of header in harder rock than last week, and growing harder, requiring to be blasted.

(Continuad on Page 84.)

Leaching Process.

A correspondent of the *Bulletin*, writing from La Paz, Lower California, says:

Mr. Brooks, now sole owner of the Hermenegera company's mines, has 250 tons of silver ore in town, awaiting shipment to Europe, that will essey $150 to the ton. The prospects of this company ware never before so flattering as now. The lixiviating process hes proved a complete success, and tha company heve thrown ont their pans and barrels, thus seving a great amount of power. The adoption of this process has saved the company at least $200 per dey, while it has materially increased the yield of the ore. The fineness of the silver that never before averaged more then 760 fine, is now nearly pure, averaging 970 fine. No quicksilver is used for the process. The ore does not require to be crushed as fine, neither does it require as much roasting as when reduced by the pen process. No expensiva machinery, constently wearing out; only a tew wooden tanks are reqnired. Its adoption in Neveda wonld not only save millions anunally in expensas, bnt would increase the yield of the mines.

The Molege copper mines are yielding immense quantities of high grade ore, all of which goes to Europe. The American ship *Southern Cross*, now here taking in orchilla, will sail in a few days for Molege to complete her loading with copper ore. Perhaps Uncla Sam will begin to think he had tbe wool pnlled over his eyes when he ellowed the British Minister in Mexico to chisel him ont of Lower Californie, that England might continne to enjoy a monopoly of the trade of the west coast of Mexico. This trade of right should belong to us, and would hut for tbe supineness of our legislators at Washington and the merchants of Alta California. A reciprocity trade with this country would work great benefit, especially to Mexico, developing many new industries.

Stump Removing With Dynamite.

We reed in one of onr interior exchanges of the trouble which was experienced in removing some large redwood stumps, some times 20 kegs of powder being exploded nnder a single stump. Our memory is thus freshened by accounts in our English exchanges of a public trial which was made of tha recently iuvented explosive, dynamite. Although this substanca bas been in use for some little time as a blasting agent, wa are not awara that it has been tested for farmers' use in stnmp pulling. A number of experiments were made in the presence of a committee of farmars. Several stumps which had been digged up were split into stove wood with a few ounces of dyuamite. The experiments were concluded by blowing bodily out of the ground a large intact oak root; this was done by meking a crowbar hole between the ties or manor roots and inserting a charge of dynemite under the center. On the shot bsing fired, the root was lifted completely from its bed.

ELECTRIC TIME STANDARDS IN PARIS.—There is in Paris a committee for the automatic regulation of the pnblic clocks. This has appointed a sub-committee, MM. Le Verrier, Tresca, Breguet, Wolf and Du Moncel, to take measuras for tbe constrnction of four standard time measnres, to be set np in Paris at tha Palais de la Bonrse, at the Arts et Metiers, the Observatoire, ths Western station and St. Lazare (right bank).

The Engineer.

The East River Bridge.

The Naw York *Tribune*, in spseking of this enterpriss, says: The work upon the Brooklyn bridge seems to many to occupy much mors tima thau is necessary, and it is difficult for them to comprehend the vestnsss of the undertaking. But ons visit to the ground, a glance et the plans end drawings, and a few minutes' conversation with the angineer in cherge, will convince the most skepticel of the colossal character of the enterprise, end that there is no unreasonable delay. The immense blocks of stone, weighing four or five tons or more, swinging in the air as they are liftad to snch a dizzy hight; tbe incessant creeking of the derricks which lift them; the shouts of the foremen giving their directions; the constaut ring of tbe mason's trowel, end the buzz consequent npon the assembling of such e large number of busy lehorers and the working of so many machines, will carry tha convict on, es tha eye rests npon four enormous structnres —the towers end anchor piers—thet much time is necessary to tha completion of a work so gigentic and important. The deteils given by the engineer show thet the work is carried on from day to day with greet cere and exactness, and that it would be almost impossible to hasten what ought to be done slowly and with care to meke success sure. The preparatory work on the masonry of the different piers is now drawing to a close, end the snspension of the temporary bridge, it is now expected, will be begun ebont tha first of Angnst. The manufecturing of the cebles hes been given to a Brooklyn firm, end it is supposed that the work will be ready for them by the time that they ara completed. It is estimeted that it will take about two weeks longer to get the masonry in readiness, and that by the end of the month the derricks will be raised and a part of tha necessary machinery erected npon the tops of the piers. A foot bridge will he thrown across the river about 200 feet above the weter. Upon this tbe workmen will pess back and forth, suspending end erranging the parts of the temporary bridge which will precade the finel superstructure, and looking very much lika spiders npon a single threau, weeving a tremendous web. When the cebles are stretcbed they will be festened to the mein piers and continued to the enchorage piers, where they will be mede fast to immense cheins bnilt into the masonry. These cbains ara in themselves a marvel of construction. They are called chains because composed of links, but each link is nearly 15 feet long, three by nine inches squere, and there are from eight to ten of them, lying parallel and side by side in each chain, bolted one to another. There ere four sucb chains, heving in ell 856 links or bars, the total weight of iron being 1,000,000 pounds in each enchorege pier. Each one of these piers covers six city lots and contains nearly 30,000 cubic yards of solid mesonry. In all the pisrs the blocks of granite are laid with narrow spaces between them, which are filled with concrete well beeten down, leaving no cevities, and forming a mass of mattar, when the concrete has hardened, as remerkable for its solidity as its size.

A Great French Canal Proposed.

Frenoh enterprise is not content with the glory which the genins and energy of M. de Lesseps have reflected on his country. Frenohmen ara bent on thoroughly reclaiming for themselvas the pre-eminence they enjoyed in the seventeenth centnry for inventions to facilitate interconrse between remote localities. The project for securing throngh water commnnication hetwean the British channel and the Mediterraneen is, we are told, sariously taken np in Franca. Delegatas from chambers of commerce have formed a oommittee to advance tha proposal; and, whatever we may think of the headlessness of French speculators on the Paris Bonrse, the caution and prndence of the French merchent are established. Men of bnsiness, like the commercial classes among onr neighbors, as distinguished from the bangers-on at the centers of specnlation, do not wasta their time in idle inquiries or pladge tbemselves recklessly to ambitious undertakings; and vast as is the extent of territory to be traversed by such a water-way as that proposed, a little examination of the French map shows that some chennel of the kind is by no means difficult of constrnction. Great highways of commerca are provided by nature in the mighty rivers that traverse the country ou the west and on the south. The task of the engineer is to connect some two of these channels, so as to form one great cenal.

Already for purposes of internal commerce much of this work has bean done. The chief French river discharging itself into the English channel is the Seine. This river is nev agable in one sense or another for 340 miles, and for 100 years past has been connected with the watarshed of Mediterranean France by means of the Canal de Bourgogne. This canal runs from tha Yonne, one of the most important of the sontheastern tributaries of the Seine to the Saone, and thence tha stream of commerce is carried nearly dne sonth, by Lyons, into the Rhone and on to the Mediterranean. The proposal of the engineers is to widan and deepen the channel just providad, so as to secnre a complete water-way from Havre to Marseilles. The Minister of Public Works thinks the estimate of the committee, thet the cost of providing such a pessage for vassals of 200 tons burden would only be about two millions end a helf, must be consfdared sanguine; but his view ssams to be tbat there is no resson why such a work, if its practicability were once demenstrated, might not be completad with advantege at a mnch greeter expenditnre. In the present case ths difference of level doss not seem likely to prove of serious consequence except at Lyons, the jnnction of the Seona and Rhoue. Even thare ths enginssring skill which proposes to conquer tha difficulties occasioned by the shellows of the Saone will bsfore long provide against the sudden descent to ths Rbona, and were the wey onca open for vessels of considerable burden, the necessity of transshipment at Lyons would probably be soon obvieted.

Hell Gate Excavations.

Generel Jobn Newton, of the engineer oorps in charga of the Hell Gate operations, stetes that the explosion at Hellet's point certeinly will not take plece until September 1st, et the earliest. Although tha work of excevation is completed, the contracts for explosive materiels heve not been filed. The battery for exploding the charges will be placed near the edga of the pit; the operating room will ba about 350 feet from it. The explosive meteriels nsed will be nitro-glycerine and its various compounds, in cherges not exceeding ten pounds each, and pleced at points wbera they will be most effective, differing in this respect from the explosion in San Frencisco harbor, where the powder wes messed together. General Newton explained that the weter not only would act as a temping or covering, preventing by its weight an intense report end shock, but thet the enormous emount of beat genarated from the liberated gesas would spend its force in vaporizing tha weter, thus lessening the chences of merked egitation on the surfece. It is not expected thet much, if eny, rock will be thrown above the water, exoept where the bedrock may heve weak spots or seams. In such cases the explosion will have more effect, and throw the rock some distence in the air. The object of dispersing the nitro-glycerine is to effect a rending of the rook, so that it can be more effectually broken np by after blests. The works cover three acres, and the emount of debris which will have to be removed is estimated at not lass than 30,000 cubic yards, requiring about two years' further work.

General Newton expressed as his opinion that the scientific delegations which have epplied for the privilege of making determinations in reference to the rapidity at which sound travels in eerth, eir and weter, will be disappointed in the results of very many of their calculations, especially those which propose taking stations at some distance from the work. He anticipatss no remerkable report or violent concussions, owing to the distribution of the nitro-glycerine though so large en area end in such small quantities. The effect of the blast, to use the General's own words, will sound very much like "an explosiou in a tnb of mnsh!"—*N. Y. Tribune.*

Strength of Rail Joints.

At a late meeting in the hall of the Manchester (England) institution of civil engineers, the following paper was read: The introduction of the plain fish-plates now ordinarily used was a great advantage at the time to the railway world, mainly for preventing accidents by keeping the rails in position laterally, but since speed has increased, and weight of engines also, the plain fish-plates have been fonnd deficient in one vital respect, viz., that of giving the rail joint the same stiffness and elasticity as the solid rail, so as to obtain one continnous road. As the stiffness of the joint with plain fish-plates principally depends npon the section of the rail and the fishing angle, often only a third of the stiffne s of the joints is afforded as compared with that of the solid reil, but even in the best ceses hardly more than half the rail stiffness is obtained. Tbe introdnctiou of steel rails necessitating the abolition of notches in the rail flange as destructive to the strength of the rail, has led to the design of the Frenoh or German fish-pletes (*eclisse arret*) adepted for suspauded joint, but requiring base plates at the joint sleepers. Evan with this plan tha experiments show only two-thirds of the strength of the solid rail is obtained, and as only one fish-plate of this description is generally nsed, there is still less stiffness. Several other plans exist, more or less complicated, but as none hava yet given the same stiffness as the rail, combined with cheapness in cost and maintenance, they have not come into general use, and the weak joint, with ordinary plain fish-plates, is still generally adopted. This has given rise to the design of the dsep fish-plate for flange rails, similar to what has been already adopted for donble-headed rail sections on many English railways. By using one fish-plata of this kind on tha bolt-head side of the joint a metarial improvement is obtained, inasmuch as such joint possesses 80 per cent. of the stiffness of the solid rails. As ragards the use of two deep fish-plates the experiments are conclusive as to the great increase in stiffness, being aven stiffer than the rail, both as regards strength and elasticity. Experimeuts on two feet supports show a load of 35 tons with more deflection on tha rail than on the joint, proving a slight superiority of the joint, evan in this respect best shown hy the fact that the bolts were not the least hurt after snch an extremely heavy test.

Silver in Australasia.

The Grahamstown (N. Z.) local paper says: It would seem that this colony is about to add to the list of its productions the article of silver. This metal has lately been produced in immense quantities in different places—to such an extent, indeed, that it has become a "drag" in the market, and the value of silver is likely to be permanently reduced. That, however, probably matters little to us. The price of silver per ounce is not likely to be much affected, and our New Zealand mines bid fair to produce the metal in such quantities as to be of importance to the colony. A few days ago we stated that Mr. Masters, of the Thames, had brought up from Nelson two and a half tons of the ore, which he was about to submit to a fair test, producing from it the metal as it will be sold. Mr. Masters' skill as an assayer is fully acknowledged, and we are sure that he would not make statements which might injure his professional reputation if they turned out fallacious. Repeated assays of ore have been made, and the conclusion drawn by Mr. Masters is, that the reef will produce 300 ounces to the ton of silver ore. Some pieces, such as those shown in Messrs. Morrins' window yesterday, will produce 600 ounces to the ton, and Mr. Masters believes that he is on the safe side when he makes an estimate of 300 ounces. Mr. Masters is now erecting blast furnaces, in which the ore will be reduced by smelting, for which it is exceedingly suitable. It is believed that the copper in the ore, supposed to be about 18 per cent., will pay nearly all the expenses of working, leaving the silver as profit. Silver is at present worth about 4s 4¼d per ounce, so it would seem that each ton crushed will yield a profit of £60. It will be Mr. Masters' endeavor, in treating the ore, to produce a commercial article having about 1,000 ounces of silver to the ton, and worth about £250 a ton. This article will be in pieces of about one cwt. each, which will not require bagging, and each block can be strictly assayed. The furnace will be completed in about six days, and a most practical test can then be made, and a method of working established. We quote the following particulars as to the mine and company from the Nelson *Evening Mail:* "To satisfy numerous inquiries respecting the mine at Richmond hill, in the Para Para district, we are glad to be enabled to present some information derived from an authentic source. The Richmond Hill mining company, which was registered under the Joint Stock Companies act about two months ago, has been formed to work 320 acres of ground leased from the crown, seven miles from Collingwood, for minerals other than gold, silver being the main object, though lead and copper are also present in the metallic veins in such large proportions as to make it probable that their extraction will add materially to the profits. The lode richest in silver on the lease shows itself a few feet above the summer level of the Para Para river in a deep gorge which the latter has cut for itself through high cliffs of soapstone down to the harder formations, gneiss and clay slate, which form its present bed, The central, and silver-bearing portion of this lode, where it crops out, is about three inches thick, but, in proportion as it is sunk upon, it is found to widen out, as is usual with argentiferous veins. The general manager of the company, Mr. John Masters, who brought with him from the Thames the very highest character for metallurgical skill, has also undertaken the direction of mining operations, and since he commenced sinking on the lode has seen reason to express himself in sanguine terms as to the prospects of the mine. The nominal capital of the company is £18,000, in 1,800 £10 shares, of which 1,500 have been issued. Three-fifths of the shares are held, and three of the five directors reside in this province, the remainder in Auckland."

Works in the Illinois River.—The Illinois river is now being improved on the slackwater system. The *Engineering News* says: "Five dams will be required from Peru to the mouth, to secure seven foot navigation. The locks will be built 350 feet long and 75 feet wide, allowing of the passage of boats of 300 feet length and 72 feet width. One dam at Henry is now completed, securing the desired navigation for a distance of 25 miles. A second at Copperas creek will be completed during the present season. This dam will give 60 miles additional slackwater. When the five dams are completed no doubt the Illinois canal will be enlarged to corresponding dimensions. The length of the Illinois and Michigan canal is 96 miles. Of this, three miles is the Chicago river, which will need no enlargement; 33 miles from Bridgeport to below Lockport will need enlargement as a canal; the remaining 60 miles of canal will probably be abandoned, as the upper river can be improved on the same system as the lower river. The total lockage is 145 feet. When this improvement is complete throughout its entire extent the largest class of Mississippi boats can make the harbor of Chicago."

A Steam Velocipede.—A Berlin mechanician has invented a steam velocipede which is said to answer admirably. The engine is heated with petroleum, and being placed on the two back wheels, does not interfere with the convenience of the driver.

Statisticians estimate that there are now at work some 200,000 steam engines, with a total power of 12,000,000 horses, corresponding to the muscular strength of 100,000,000 men.

Useful Information.

A New Resin.—A process has been discovered and patented by Prof. Walter P. Jenney to utilize coal tar and convert it into a resin resembling shellac somewhat in properties and appearance, and possessing many new and valuable properties, which indicate that it will soon take its place among the resins and varnishes in the market. This new resin is dark garnet red in color; when bleached it is a fine golden amber; is tasteless, odorless; fuses at a higher temperature than shellac, and is insoluble in dilute acids, but dissolves in concentrated sulphuric acid; it is unattacked and insoluble in alkalies; even fusing caustic soda has no action on it. It is soluble in oils, coal tar, naphtha, in benzole, chloroform, ether, bisulphide of carbon, and in petroleum naphtha, but not in alcohol or water. When made into a varnish with suitable solvents, it leaves on drying a brilliant and permanent film, which shows a remarkable property, and not the slightest tendency to crack off; a thin coat of it renders cloth or paper water-proof as rubber; in fact, it dissolves rubber either pure or volcanized. For japanning tin or ironware, it is even superior to shellac or linseed oil alone, the surface being hard and wonderfully pliable. On tinware it produces, with linseed oil, a beautiful golden enamel, which a few hours' baking in an oven makes fine and adhesive.

Glass from Blast Furnace Slag.—We have lately had an opportunity, says *Engineering*, of examining several specimens of glass manufactured under the patent of Mr. Bashley Britten. The process consists in using the slag from iron furnaces in its liquid state direct from the blast furnace. The slag is conducted while in a liquid state into a tank holding about 15 cwt., where it is mixed with other materials, and in an incredible short space of time, as compared with the ordinary method, glass is produced. This glass is acknowledged by the workmen to be of an exceedingly soft or plastic nature. It is perfectly acid proof and capable of use for all purposes for which the best bottle glass is suitable. It cuts readily with the diamond, and is available as rough plate for roofings, skylights, greenhouses, roofing tiles, and for many other uses from which glass, as heretofore manufactured is, on account of its cost, necessarily shut out. Specimens have also been produced of this glass colored brilliantly, and suitable for the purpose for which colored glass is employed. A private company has been formed and will shortly be registered with a capital of £200,000, for carrying out the manufacture of glass under this patent on an extensive scale.

British Mining Statistics for 1875.—The reports of the Home Office of the inspectors of mines throughout the United Kingdom for the years 1874 and 1875 have just been issued. The whole produce of coal during the year was 133,306,485 tons, compared with 126,590,108 tons in 1874. The production of fire clay was 1,932,294 tons, compared with 2,067,791 tons in 1874. The yield of ironstone was 12,018,594 tons, against 11,693,186 tons in 1874; and the produce of shale (almost wholly in Scotland) was 442,940 tons, contrasted with 362,747 tons in 1874. These figures show an increase of 6,716,377 tons of coal, 325,508 tons of ironstone and 80,193 tons of shale, and a decrease of 135,497 tons of fire clay. This immense production was the work of 535,845 persons, whilst the number so employed in 1874 was 532,829. Of these 427,017 were employed underground, and 108,282 above ground, as compared with 428,611 and 110,218 respectively in 1874. Of these, 11,507 were under 13 years of age, 10 of them being females. In 1874 the number under 13 was 12,816, of whom 22 were females. The total number of females employed was 6,504, whilst in 1874 the number was 6,899. None of these were employed underground.

A Suggestion to Owners and Users of Steam-Power.—Accidents arising from the entanglement of some portion of an operator's garments in a swiftly revolving shaft, are of too frequent occurrence in large manufactories, and of a distressing or fatal character. Many suggestions have been made, from time to time, to prevent or at least lessen the chances of such accidents. One of the simplest methods of rendering these casualties impossible, without introducing the necessity of constructing a railing or fender about the moving piece in dangerous places, is to cover the shaft with a loose sleeve along its entire length. This may be made of sheet-tin or zinc, and to be removable if desired. It should be covered within and at the ends with leather, to prevent noise. Arranged in this manner, the friction between it and the revolving shaft would be sufficient to cause the sleeve to rotate with the latter; but in the event of any decided resistance being brought to bear upon it, as in case of the entanglement of a workman's garment, the sleeve would at once be brought to rest and permit of extraction without accident. The same idea of loose covers may be applied to cog-wheels or pulleys, and prove an invaluable protection against loss of life or injury to person.—*Manufacturer and Builder.*

Red Ink.—The following recipe for a beautiful red ink is given by Metra, of Paris: Dissolve 25 parts, by weight, of saffranine in 500 parts warm glycerine, then stir in carefully 500 parts alcohol and an equal quantity of acetic acid. It is then diluted with 9,000 parts water, in which is dissolved a little gum arabic.

Experiments on the Fading of Colors.—It has been observed by Kœchlin that woolen cloth dyed with indigo had its peculiar blue color notably diminished by being exposed to a freezing temperature. According to some experiments made by Goppelsrader, this discolorization is due to ozone present, which acts at temperatures below zero, but only when the tissue was wet. Cochineal reds on wool seem to lose their brilliancy when exposed to the action of ozone for eight days. Aniline black was unchanged, but aniline brown on cottons was turned into a yellowish brown. Magenta, aniline blues and violets, and iodine greens were unchanged, as were lakes and strong colors, as Turkey red. Ozone seems, however, to have in some instances the property of developing and intensifying certain colors, more especially the aniline blacks.

The Right to Demand Overtime.—The right of an employer to claim overtime work from a workman has been established in an English court. In the case the plaintiff stated that in October of last year he was engaged to work at the Darlington forge as a metal turner, and he remained there till May 24th of the present year. On that day he was told by one of the clerks that he was to go back in the evening and work overtime; but he left off at five o'clock as usual, and did not return until six o'clock on the following morning, when he found that his board was stopped. On making inquiries as to the reason for this, he was informed that it was because he did not return to work on the previous night as desired. He was not allowed to resume work again, and hence the present claim. It was stated for the defence that there was no wish to deprive the plaintiff of any wages that might be due to him, but the present claim was defended on principle. It involved the important principle of whether they could not, when it was required, compel their men to work overtime, unless they alleged reasonable excuse for refusal. The judge held that the plaintiff had tacitly agreed to work overtime before he left, and as he had failed to do so, and was without reasonable excuse for the failure, judgment was given for the defendants with costs.

Grape Refuse Vinegar.—Where grapes are made into wine, a fine article of vinegar can also be produced. Take the stalks of the grapes, and the skins and seeds, and let them heat in a vat or tub for four or five days; then to about every 30 pounds of the refuse, add four gallons of water, and stir it up well. Repeat this process three or four times a day for two days, then strain or squeeze out the liquor into a cask or tub, and dip a slice of bread into a teacupful of yeast, and add the whole to the liquor. Let it work until it ceases to hum, then cover the bung hole with a bit of wood, and let it remain until well soured, which will be in a few days, if the weather is warm. Then put it into a cool cellar, and if it looks a little muddy, mix a quarter of a pound of isinglass, with just enough cold water to cover it; let it stand ten minutes, and then turn over it a pint of boiling water, and let it boil until it is dissolved, and turn it into the vinegar. In a week or so it will be perfectly clear, and can be kept tightly bunged up.

Good Health.

Guard Against Contagious Diseases.

The following excellent practical directions for combating infection and preventing the spread of the "catching" diseases, such as small-pox, measles, typhus, scarlet fever, etc., embodying the measures recommended by eminent medical authorities, may be adopted with all confidence as suitable and efficient:

House Ventilation.—Keep rooms and passages sweet by opening windows and doors for the admission of fresh air. A fire with windows open greatly promotes ventilation. The burning of coffee or sugar also enhances the effect of ventilation.

Drinking Water.—See that the water pipes are clean, and in every case filtration is a very desirable precaution.

The Sick Room.—Remove bed curtains, window hangings and carpets. Use ventilation continuously, supplementing by the burning of coffee, sugar or with disinfectants, sprinkled from time to time on the floor, and inhaled into the air by means of a spray-producer. Place a dish or soup plate containing disinfecting solution underneath the bed occupied by the sick. Empty utensils as speedily as possible, and on replacing them in the sick room, throw in some disinfecting fluid. To all water used for cleaning, washing and scrubbing, add a small quantity of disinfecting fluid. Keep within reach of the patient a basin similarly charged with disinfectant for him to spit into, and have close at hand a tub or pail of diluted disinfecting fluid, into which immediately throw any article of clothing removed from the patient. Instead of a pocket handkerchief, let him make use of small pieces of rag, which are to be burnt after use. Hang outside of the door or room, from jamb to jamb, a sheet or old counterpane, and keep it moistened with disinfecting solution.

Infected Clothing or Bedding.—Linen and woolen articles, as admit of washing, on being removed from the patient should be plunged for 24 hours in a tub of water, diluted with disinfectant, and immediately washed afterward, which can be done with impunity. Cloth, clothes, mattresses, beds, pillows, etc., in the absence of a public disinfecting oven or room, are to be disinfected by exposure in the open air to the sun, if possible, or in front of a large fire, and thoroughly smoked by burning coffee, sugar, or other aromatics.

Nurses and Attendants.—Woolen dresses are to be avoided; and the preference given to washing materials. Prevent contact, as much as possible, between attendants and the inmates of the house. After handling the sick, or things connected with them, let the nurse be careful immediately to wash his or her hands in water impregnated with disinfectant.

The Patient.—As soon as may be admissible, anoint the surface of the body, the scalp or skin of the head included, twice a day with camphorated oil. The earliest appearance of scaling off of the scurf-skin will furnish the indication of the period beyond which this measure must not be delayed. When the patient has gathered sufficient strength, let him take a warm bath, to which has been added some disinfectant, and afterward be washed with soap and water. During a week or ten days from this time he may be kept apart, repeating daily the disinfecting ablution; after which he can, with safety, mingle again with the family.

Disinfectants.—The best known disinfectants are chloride of lime, Condy's fluid chloride of zinc, carbolic acid, camphor, carburate of camphor, bisulphate of soda, green copperas, Labarraque's solution of chloride of soda, salicylic acid. When doctors disagree, who shall decide? Either of the above are efficacious, and objectionable to some of the medical profession. But what chemical substances are truly disinfectant? According to the eminent chemists, Dumas, Chevrieul and Tage, certain chemical substances are serviceable in neutralizing unpleasant odors, while other chemicals are required in order to arrest the fermentation or decomposition of the decaying tuberances which produce the epidemic, influenza, and bad odors. For example, while chlorine, chloride of lime, zinc, and nitrous fumes are well known neutralizers of the odors of sulphureted, carbureted, phosphoreted hydrogen or ammonia, they have no power to arrest the decomposition whereby those odors are produced. This, moreover, is accomplished readily by carbolic acid, phenyl creosote, and especially carbolate of camphor, which act like tannin upon all albuminous substances and prevent further decomposition. But carbolate of camphor has a double action. While it stays dead muscle upon contact, it kills every living spore it touches, and thus, what is now believed to be the active principle of all contagious diseases is rapidly attacked and destroyed, and is therefore admitted to be the great scavenging principle of nature—a most powerful cleansing, neutralizing remedy. The combination and preparation, in a suitable fluid form, of the properties of carbolate of camphor, afford the means of bringing to bear, at any particular time and place, this most remarkable and effective agent in arresting and preventing contagious diseases.

From dead bodies all chance of infection will be prevented and all effluvia destroyed by wrapping them in sheets saturated with a solution of carbolate of camphor.—*Dr. L. Lanszweert.*

Beware of Poison in Toys.—The sanitary inspector of Glasgow (Scotland) has found that the yellow toy balloons sold to children are poisonous. He says that the coloring matter consists of one part of chromate of lead and three parts of carbonate of lime. Children, being in the habit of applying their mouths to the orifice of these balloons for the purpose of filling them with air, may readily receive a quantity of such poisonous powder into their mouths. Toy balloons, therefore, although admirably fitted for playthings at baby farms and other institutions of a similar character, should be viewed with supicion in every well regulated nursery. That colored candies sometimes contain poisons is well known, and those also should be avoided. Many other painted toys should be suspected, especially the bright colored ones, which most always are of a mineral nature, and if not directly poisonous are certainly injurious to health. As there is an abundance of good toys without colors or paints, there is no necessity to get suspicious looking things for children, and all small colored or painted toys adapted for use on the table, and which babies may put into their mouths, should be banished from a nursery. The paint on large objects, like sleighs and wagons, is of course not so apt to do injury as that on small objects.

Is Lead Pipe Unhealthy?—The question whether there is danger from the use of lead pipes for the conveyance of drinking water, is discussed by M. Belgrand from a rather different point of view from that which has been usual. He calculates the length of lead pipe used for this purpose in Paris, and shows that the water remains in contact with the lead much too short a time to be acted upon. As interesting specimens, he some time ago exhibited to the French academy two pieces of lead pipe, the one laid down two centuries back, the other at a period somewhat later. The inner surfaces of these tubes, notwithstanding the fact that one of them had conducted water for a period of 200 years, were both completely intact. The direct experiments with reference to this same question, made with such care by MM. Dumas and Lebtanc, are of similar import; that is, distilled water was found slightly to attack the lead, while river, spring and rain water has no appreciable action on the metal.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Improvement in Condensers; Quicksilver; The Harbor Commissioners' New Tug-Boat; Stone Implements; Machinery at the Fair, 73. Respiratory Apparatus for Miners; The Engine for the Fair; Comstock Papers; Mechanical Ore Concentration and Separation, 80. Alpine County Its Mines and Resources, Past, Present and Future; Howell's Self-Adjusting Brake; The Coming Industrial Fair; How Valuable Mines should be Recognized, Prospected and Worked; The Silver Question, 81. Patents and Inventions; Mining Accidents; Foundry Work, 84.

ILLUSTRATIONS.—A Cheap Condenser; Indian Stone Implement, 73. Howell's Improved Patent Wagon Brake, 81.

CORRESPONDENCE.—Placer County Mines; Gems and Precious Stones, 74.

MECHANICAL PROGRESS.—How to Build a Machine Shop; A New Weapon; Blown Cast Iron; Testing the Strength of Chains; "Centennial Chimes;" Strength of Iron and Steel Plates; American Lumber for England; The Fastest Cable Telegraphy; An Easy Railway Car, 75.

SCIENTIFIC PROGRESS.—Apparatus for Demonstrating the Transformation of Force; New Telegraph Apparatus; Origin of Petroleum; How the Toughened Glass is Made; How French Colors are Produced in Glass; Measuring Distance by Sound, 75.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 76.

MINING SUMMARY from various counties in California, Nevada, Oregon, Montana, Idaho and Utah, 77-78-84.

THE ENGINEER.—The East River Bridge; A Great French Canal Proposed; Hell Gate Excavations; Strength of Rail Joints, 78.

USEFUL INFORMATION.—A New Resin; Glass from Blast Furnace Slag; British Mining Statistics for 1875; A Suggestion to Owners and Users of Steam Power; Red Ink; Experiments on the Fading of Colors; The Right to Demand Overtime; Grape Refuse Vinegar, 79.

GOOD HEALTH.—Guard Against Contagious Diseases; Beware of Poison in Toys; Is Lead Pipe Unhealthy, 79.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 84 and other pages.

MISCELLANEOUS ARTICLES.—The Silver Bill, 74. Leaching Process; Stump Removing with Dynamite; Electric Time Standards in Paris, 78. Silver in Australasia; Works in the Illinois River; A Steam Velocipede, 79.

THE BERKELEY RAILROAD.—The Central Pacific railroad company have completed the track laying on the branch road to the State university grounds. The ferry commutation tickets for August are good for a passage to "Oakland, Alameda and Berkeley." It is stated that the company have a grading force, which is to be immediately increased to some 400 in number, at work on the main line of the Oakland and Bantas road, making the grade from Berkeley towards San Pablo. It is still said to be the purpose of the company to have the road completed to junction with the Western Pacific, near Bantas, early in the coming year.

A KIND REMEMBRANCE.—We acknowledge a kind remembrance from James Lick, Esq., freighted with six boxes of fine fruit from his farm at San Jose. The cheer is refreshing and the remembrance encouraging to the workers on the PRESS. Mr. Lick is frequent in his kindnesses, and his compliments to the literary toilers of the PRESS extend over many years. For the information of some fruit packers it is interesting to note that Mr. Lick's fruit is of uniform quality from top to bottom of the box.

METAL AND FUEL FROM ENGLAND.—During the week ending June 24th, the following amounts of metals, hardware and fuel were shipped from ports of Great Britain for San Francisco: Pig iron, 1,144 tons; 24½ tons of manufactured iron; 250 tons of old rails; 7 tons of iron tubes and pipes; 18 packages of hardware; 1,750 boxes of tin plats; and 7,113 tons of coal.

Respiratory Apparatus for Miners.

Not only in coal but in metal mines it is sometimes necessary to enter places filled with deleterious gases, either to carry aid to miners or to explore old workings. A number of contrivances exist to provide a respiratory apparatus, carrying a supply of fresh air. A very good one is that of Mr. Rouquayrol, a French mining engineer. In this the reservoir is made of sheet iron, capable of resisting from 25 to 40 atmospheres. Air is forced into it by means of ingeniously contrived pumps, the pistons of which are fixed, while the cylinders are movable. The apparatus is fastened on to the back like a soldier's knapsack. A contrivance consisting of a kind of bellows, placed above the reservoir allows the air, (although greatly compressed) to enter the lungs at the ordinary pressure only. A small external valve formed of two leaves of rubber, which are kept in contact with each other by the pressure of the atmosphere, open to allow the escape of the air respired. In this apparatus, at the same time as it is breathed the air is sometimes supplied to a lamp especially constructed to burn in an atmosphere in which a common lamp could not be used.

Provided with Rouquayrol's apparatus a man can breathe with ease even under water, conclusive experiments having been made on the beds of rivers, etc. The apparatus might sometimes be found useful in mines for working under water, at the bottom of sumps for instance, for upraising broken pumps, cleaning out pipes, etc.

A simpler contrivance than this, and just as effective for some purposes, is the system of injecting air into an air-tight goat skin by means of a small bellows. The man carries this on his back, keeping it in place by straps around the shoulders and waist. Two india rubber tubes are fitted to the bag, terminated together by a piece of horn or ivory, hollowed out around its circumference and held between the teeth. The nostrils are compressed by a small spring clothes pin or other similar contrivance. Lastly, when necessary, in a very hot atmosphere or in case of fire, the eyes are protected by a pair of spectacles with glasses mounted in leather.

With this apparatus, which any one could arrange quickly, the man is free in his movements. Breathing is carried on without difficulty and the air which has been respired is returned into the reservoir and may be used twice over without inconvenience, but at the end of a quarter of an hour it is necessary to renew the air in the bag. The tube through which the air passes outward opens at the upper part of the bag while the tube by which it is returned goes to the bottom. Besides the air which has been breathed, being heavier, goes to the bottom. At the end of some seconds a movement of the tongue is instinctively and unconsciously produced, which stops up or opens the swivel piece, sometimes one tube and sometimes the other, according as the lungs inhale or respire the air. This apparatus is especially useful for pump men, well workers, repairers of sewers, etc. For mines, reservoirs of tin plate may be used and the air forced in under some pressure.

The Engine for the Fair.

The large new engine which is to furnish power for the machinery at the Mechanics' fair was built especially for the purpose by the Fulton foundry, of this city. The engine, bed plate and fly wheel weigh about 10 tons. The engine is fitted with Myers' variable cut-off and Hendy's governor. It has an 18 inch cylinder and three-foot stroke. The fly wheel is 16 feet in diameter and weighs five tons.

The engine is an ordinary one such as is built at the Fulton, with perhaps a little higher finish. It is a little larger than the one used last year, which was built by the Union iron works and had a 16-inch cylinder. It is fitted with Saunders' metallic packing, which is being introduced here by the Ætna iron works. This packing is spoken of highly and we shall at some future time speak of it more in detail. The engine has been set up in the pavilion, so that there will be no delay in furnishing the motive power when the machinery is all in. It will be run a few days before beginning actual work, so that everything will be in order.

MINE CAGES.—An English inventor has patented a new safety apparatus for mine cages. Peculiarly constructed bevel clamps are used for locking the cage or platform to the guides when the rope breaks, each of which clamps has parallel bearing surfaces placed obliquely to the levers, one within the other, and pivoted cross-wise together, so that each lever thus bites on both sides of the guides. These levers may be connected in numerous ways with the platform so that its weight will cause them to bite upon the guides. Means are also provided for opening and clamping the levers.

THE railroad and stage men are said to be agitating the question of connecting Scales' Diggings by a good wagon road with Camptonville, Yuba county, so as to secure direct communication with Northern Sierra and San Francisco, via the narrow gauge railroad.

Comstock Papers.

NO. 2.

First Strike of the "Black Stuff." Conflicting Claims and their Adjustment. How the Great Washoe Lode Came to be Named.

As already related, the discovery of the Comstock lode at a new point near the present site of Virginia City, was occasioned by a couple of gold washers' digging a shallow pit to hold water for the use of their rockers. This event, which occurred in the month of June, 1859, was the result of the sheerest accident. These men were not hunting for silver nor ores of any kind. In so far as they had any idea about such substances, this was the thing they were most desirous of avoiding. While working up Six Mile canyon the year before, they and their companions, as they approached its head, had encountered a dark colored, heavy metallic rock, "black stuff" as they called it, which had caused them no little trouble, its weight being so nearly that of the gold obtained along the canyon that they found it difficult to separate the two in their rockers. All the gold dust gathered in that region of country, containing a large percentage of silver, was much lighter than the average California duet, and consequently more difficult to save by the process of washing. When, therefore, these honest miners detected in the pit they had sunk the presence of this detestable stuff—the rich sulphurets of silver, they were disgusted thereat, and would have heaved it aside and paid no further attention to it had they not found mixed up with the earth thrown out a considerable amount of free gold. This was an article with which they were acquainted—was, in fact, the thing they were searching for, wherefore they at once proceeded to take up a surface or placer claim at that point.

A Multiplicity of Claimants to the New Discovery.

Now, so it was, this precise spot happened to be within the bounderies of the ground located by Finney the year before, or this, at least, was the view this old man chose to take of the matter, and not, perhaps, without some show of reason, as it was then the custom of the district to make square locations in taking up both quartz and placer claims, and it might well have been that his claim, the croppings on which lay only a few rods further west, included this spot within its limits. Joseph Kirby, who had previously been washing along a small ravine a little below this place, also advanced some sort of claim to an interest in the new discovery, there being several others who, upon one pretext or another, were seeking a share in it.

Affairs being thus complicated,

Henry P. Comstock,

An old resident and common friend of all the contestants, was elected, or perhaps elected himself, to act as umpire in the premises; an office he seems to have performed to his own satisfaction, and for aught that appears to the contrary, to the satisfaction of all concerned. In adjusting the business it was so arranged that the umpire appeared on the record as the owner of most of the property in dispute, he having first awarded it to Finney, and then bought the latter out. The claim in question covered what are now known as the Bonanza mines, and also a part of the present Ophir ground. Within a year from the time the above transaction took place, it sold for a million of dollars. That the other parties to this contest should have so readily yielded their pretensions and acquiesced in the disposition thus made of the property is explained by the fact that they did not consider it of any special value, and had not, probably, much confidence themselves in either the justice or validity of their claims.

He Receives for his Mine an Indian Pony and Something to Drink Beside.

The consideration that moved the vendor to make over his estate in this mining claim consisted of a certain Indian pony, bob-tailed, lean and aged, of which the purchaser was then and there possessed, this constituting the sum total of his available effects, save only a scanty supply of cabin traps, a roll of blankets, a gold rocker and a rifle, with a reasonable stock of whisky and tobacco, without which latter, existence with these early dwellers on the "Eastern slope" would have been intolerable, if not wholly impracticable.

While Finney did not guarantee title to the ground sold, the transfer thereof having been effected by simple quit claim deed, he did, on the other hand, require that his friend should in the bill of sale assure title to the animal made over to him, the abbreviated caudal appendage of the brute and some other marks about him pointing to a former ownership by the Piutes, against any claim from which quarter the old man was naturally desirous of protecting himself. According to some authorities, divers bottles of exhilarating fluids formed part of the consideration by Finney received on that occasion; a fact which no one having any acquaintance with the convivial habits and commercial usages of these Washoe pioneers will feel inclined to call in question. Indeed, that class of persons may be said to infer that they know that such was the case, a drink all 'round having been with these pioneers not only a pledge of friendship but a token with which they sealed all bargains.

He Sells His Claim to a California "Rock Sharp."

Very soon after he had acquired this claim, Comstock disposed of the greater portion of it to Judge Walsh, an enterprising and experienced quartz miner of Gress Valley, who, having heard of this discovery and seen some of the rich ore brought to his place, hastened over the mountains for the purpose of examining the deposit and making a purchase thereof, if the thing looked favorable. How little appreciation Comstock himself had of the real value of this property is evinced by the fact that he parted with his interest in nearly the whole of it for $6,000, congratulating himself that he had been able to dispose of it for even that much, and joining with his associates in making merry over the manner in which he had taken in what they facetiously termed, "the California rock sharp."

How His Name Came to be Conferred on the Lode.

In making out the deed whereby this claim was conveyed to Walsh, it was, for the want of a better name, described as the "Comstock ground," a style of description which, having been adhered to in all subsequent sales of the property or portions thereof, caused this term to be at length applied to all portions of the lode. Other than this there was no especial fitness in thus designating the great ore channel, the man whose name it bears having had nothing to do with its discovery, location or subsequent development, and who acquired all his interest he ever had in it at a very cheap rate.

[Copyrighted.]

Mechanical Ore Concentration and Separation.

(Written for the PRESS by FRANCIS F. M. CASIN, M. E., Santa Fe, New Mexico.)

Introductory.

In presenting this treatise to the public, I intend to have it understood that it shall not claim rivalry with the two scientific and complete works on the same subject, written by Rittinger and by Gætzschmann. Nor shall it compete with Guido Kustel's "Treatise on Concentration." All three very elaborate books are indispensable to the engineer following this special line of trade, but they contain too much, when consulted for a practical purpose by the mine owner. This essay has been written with the double object of propagating a correct estimation of what mineral dressing really is and of indicating the right line of action to those who are in a position to require assistance of the art of mineral dressing. These combined objects neither require a long enumeration of hundreds and thousands of apparatuses used at different places with more or less success, nor learned and elaborate examination of principles on which the action of these apparatuses is based to the extent that these three works cited above do more or less contain them.

In offering this treatise to the American public, I had to accommodate it to the requirements of the period and of localities as well as to the faculties of those connected with the mining interests, and I hope to have augmented its practical usefulness by so doing. It contains a full statement of facts and principles *as far as required for the purpose of all mine owners, adventurers and practical mineral dressers*, in order to enable them to select efficacious machinery, make efficient arrangements at the right places and to do sensible and successful work. To those only generally interested in mining it will convey the impression that mineral dressing is a trade requiring good theoretical and practical knowledge, and that it is dangerous to confide the construction of mineral dressing arrangements to persons inexperienced in the premises or lacking the proper knowledge, though they may be of great general ingenuity.

This treatise will also give such statements as will enable adventurers to judge whether their ores can be dressed or not and at what cost. The propagation of proper acquaintance with what the art of mineral dressing is able to accomplish, will bring vast wealth to this country, where enormous mineral treasures are lying idle because a majority of those to whom the mines belong or those who would work them do not now possess the knowledge of what results *mechanical metallurgy* can accomplish, and therefore do not realize what treasures are in their possession, in the shape of mines producing low grade ores. This knowledge once propagated, many will find ways and means to utilize their knowledge and will thereby produce the wealth alluded to.

LABOR AT THE EAST.—We lately had the pleasure of a brief conversation with Rev. W. W. Brier, of Centerville, Alameda county, who has just returned from an Eastern visit. He reports a general reduction of wages in almost all employments so far as he has observed. To show the condition of labor in St. Louis he said a trustworthy man told him that if he should advertise one week for hands on a public work, he could get 5,000 at 30 cents a day. He returns to California fully impressed with the fact that this State is not such a bad place for a laboring man, after all.

Alpine County—Its Mines and Resources, Past, Present and Future.

[Written for the PRESS by VICTOR HARLAND.—No. 2.]

Of the several mining districts situated in this county, there are four of which special mention should be made, and which have been and are now the scenes of operations that will be greatly extended within the next two years. These districts are known respectively as Silver Mountain, Alpine, Mogul and Monitor districts.

The operations in former years, while developing in many cases a sufficiency of ores bearing gold and silver in fair quantities, have been, in almost every instance, confined in that disastrous method of prospecting mentioned in a former article, viz: Surface

Mining by Means of Tunnels.

The general idea pervading the minds of owners during the early period of mining here, was to first ascertain the nature and dip of the veins by cutting the lodes at a short distance below the various outcrops; then, encouraged by proof in nearly all cases of the apparently true character of the lodes, they would proceed to run long tunnels, starting at a point far below their first surface explorations and running toward the lodes with the mistaken idea that as each foot was gained horizontally along the line of their tunnels, the same pro rata was gained in depth along the vein itself. The rugged nature of these localities, the hight of the mountain summits from the valleys and canyons below, and the seeming expediency of this method of working, were the actual causes that decided the experiment of tunnel mining here. In some cases tunnels of 1,500 and 2,000 feet were persistently driven through the country rock, only to cease their gigantic operations when actually compelled to by reason of the failure of stockholders and parties interested in contributing, month after month and year after year, the necessary funds with which to carry on the work. Many such enterprises have so failed before reaching the point where it was expected the lode would be intersected; others, after penetrating 500 or 600 feet of "bedrock," and cutting their lodes often at a depth equal to less than one-half the horizontal distance of the tunnel driven, were abandoned because the ore proved still refractory at these short distances from the surface, no note being taken of the mammoth proportions of the lodes or of the vast upheavals on either side, which show conclusively that with the evidences of wealth upon the surface, and at these short distances below, a perpendicular depth of reasonable proportion below their lower workings once gained, the better in both quality and quantity will become the ore.

The Ores Being Refractory

To a certain degree, though not to be pronounced base, and no process being introduced which would successfully separate the gold and silver from the baser metals, operations were allowed to languish, and, eventually, many fine locations were abandoned until some time in the future when an economical method of reduction should be introduced. The ores in these districts contain a very fair percentage of gold, and the latest developments in several of the mines therein have demonstrated the fact of an increasing value in that particular as depth is gained upon their lodes, reaching in some instances 65 and 70 per cent. of the total assay value in gold and silver.

It is believed that at

A Reasonable Depth

The refractory nature of the ores will by degrees disappear. These opinions are based not only by assertions and reasonings of scientists who have given the localities a thorough examination, but by a practical demonstration in the character of ore found in the prospect shaft of the Advance company at Monitor, at a depth of 150 feet below the adit level, or what is known as their main tunnel from the base of Monitor mountain. This ore proved by experiment to be far more tractable than that found in the upper or surface tunnel. With the present exploration of this and other companies by means of permanent shafts, penetrating their respective lodes at a depth not heretofore explored within the county, there is little cause for anxiety or fear regarding the future prosperity of these districts, for as surely as the day follows the night this inauguration of deep mining here will cast aside all doubts regarding the productiveness of these mines, as the proof of the existence of ores of good quality is of every day occurrence and cannot truthfully be disputed.

Until within the past two years, but one shaft in the county had reached a depth of 200 feet; which accounts for, in a great measure, the stagnation of business and delay in producing that undisputable evidence of the wealth of a mine or locality,—bullion. Again, many of the best locations are owned by poor men, who can ill afford the expense necessary to open and develop their claims, but having firm faith in the ultimate success attending the efforts of those companies who, having means at their command, are now moving in the right direction, have remained and protected their claims from re-location. Within the past year, many of the

Old Abandoned Claims

Have been again located, several of them by persons residing in your city, who have lately visited this county and were favorably impressed with appearances here; others, again, that have lain idle for years are receiving the attention of parties interested, who are preparing to resume operations under the original titles. In my next letter, I will begin a description of

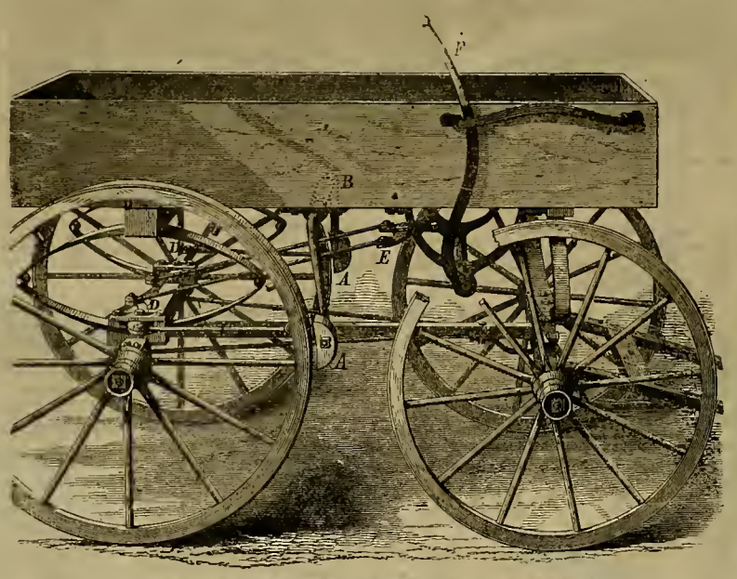
The Various Districts

And of the mines that are located therein, their extent, development, etc. I have already taken up a great portion of your columns with a general description of the appearance of the mining portion of the county, deeming it but just to point out the defects, which are attributable to an imperfect knowledge of mining in the earlier period, as well as the advantages which this county really possesses as a basis for future operations of a more perfect and systematic character than indulged in during the intervening time between the date of occupancy of these districts and the present time.

Howell's Self-Adjusting Brake.

The importance of a good brake is appreciated by all teamsters. We illustrate on this page a new brake which is highly recommended by those who have used it. The following is a description of the contrivance as shown in the engraving:

The brake shoes, *A*, are suspended in front of the hind wheels by arms of shafts, the inner ends of the latter being secured in a sleeve, *B*, (dotted lines) underneath the wagon. The shafts not being connected together, and working independently in the sleeve, *B*, it follows that either brake shoe may be pushed against its wheel without causing a like movement of the opposite shoe. To each shoe is attached a rod, *C*, which is attached to pivoted lever, *D*, and these last by rods to the evener, *E*. The levers, *B*, it will be observed, are pivoted to the rear axle, so that the direction of the forces, imparted by them to the axle and by the shoes to the wheels, will oppose and neutralize each other through the wheels and the axles. The evener, *E*, is pivoted to the end of a rod which is connected to an arm of an oscillating shaft suspended from the bolster or front part of the wagon box, and provided with a hand lever, *F*, for operating the mechanism.



HOWELL'S IMPROVED PATENT WAGON BRAKE.

The inventor claims for his brake that it has the following advantages over the common brake: It operates with greater force; it racks a wagon less than any other lock you can attach to it; it imparts an equal force to each wheel, though the diameters may not be equal; in dangerous places you can always rely upon it.

Mr. Howell writes us that many parties are taking off the old brakes and substituting his. Any further information may be had by addressing C. M. Howell, Andover, N. J.

MR. B. GOODWIN will shortly start on a trip in the interests of the PRESS through Tehama, Trinity and Shasta counties, California, and probably go even further north. We bespeak for him the courtesies of our friends while on his travels.

A TUNNEL 775 feet long was completed this month to drain the Babb claim at Timbuctoo, Yuba county. It is a costly work, and will give facilities for washing a large body of deep auriferous gravel, that has been waiting years for an outlet.

THE sulphur product at the Sulphur Banks quicksilver mines in Lake county goes a long way toward paying the expenses of the establishment, and furnishes employment for a great many men and teams.

THE *Daily Telegraph* announces that letters from Henry M. Stanley, the famous explorer, have been received dated April 24th, 15 days' march from Ukiki.

The Coming Industrial Fair.

Active preparations continue for the approaching exhibition under the auspices of the Mechanics' Institute. The internal arrangements of the mammoth pavilion have been changed to suit the present requirements, more fountains and walks added and whatever would conduce to the comfort and convenience of visitors and exhibitors has been done.

It has been decided that the opening exercises shall take place at Wade's opera house instead of at the pavilion. The exercises will commence on Tuesday afternoon, at two o'clock, August 8th. They will consist of an address by President Hallidie, oration by Henry Edwards, the reading of a poem, and vocal and instrumental music. There will be a grand orchestra and a chorus composed of 100 adults and 500 school children. The exercises will close with a grand tableau representing the different arts and industries. Those holding tickets of admission to the fair will be admitted to the opera house. This will be a much better place for the literary exercises than the pavilion, which is so large and usually so noisy on opening day, that little of the speech making can be heard.

As we have previously stated, the musical concerts will be a prominent feature of this year's fair. There will be two bands under efficient leadership. To render the music more enjoyable a partition has been run the whole length of the machinery department, so as to separate it from the rest of the exhibition and shut off the noise incident to machinery in operation. It is stated that the art gallery will be more than usually attractive this year as many contributions from private collections have been promised.

The trustees of St. Ignatius college have consented to allow an exhibition of the philosophical instruments of the college. This collection is the best on the coast without exception, especially in the line of electrical apparatus. Professor Neri will give frequent exhibitions of the powers of the electric light.

The Location Committee are still at work laying out the "space" for exhibitors and many of them are arranging for their stands, etc. There is no doubt whatever that all the available space will be occupied and that the fair will be as great a success as ever.

The following employees have been selected by the board of managers: Doorkeepers, George Harmon and John Evatt; sergeants, Mr. Brickwell and D. Delaney; watchmen, E. M. Taylor, John P. Allen, George P. Little, George Gilland, Charles Vizina, Frank Sweitzer, W. J. Newton, Andrew Duncan, A. W. Rhody, J. G. House, James F. Campbell, Peter Jenkins, Thomas Olvanney, Charles D. Smith, William B. Stevens, H. L. Barker, H. C. Osmer; janitress, Mrs. Susan H. Allen; sanitary inspector, Dr. Nimrod W. Jones; hat and cloak room, Thomas Tweedale.

MINING AND FARMING.—Hon. G. J. Carpenter delivered the Centennial oration at Placerville, El Dorado county. He said that agriculture and mining in that county are mutually patronizing and protecting, not hostile avocations. Since the discovery of gold, California has produced $1,200,000,000, of which El Dorado county must have contributed $100,000,000. He warned the farmers against checking mining industry by litigation on account of the shifting of watercourses by the sluicing process.

AN historical painting by Harrington, representing the discovery of the Comstock lode, will shortly be placed on exhibition at one of the picture stores in this city. The picture, although, of course, altogether imaginative, gives an unusually truthful representation of a mining scene.

How Valuable Mines should be Recognized, Prospected and Worked.

[For the PRESS by E. G. G.—No. 5.]

G. Amalgam.

Color, silverwhite, slightly brittle. Specific gravity, 14. Strongly heated it squirts, quicksilver separates while silver remains. Composition: quicksilver, 65.2 or 73.75; silver, 34 8, or 26 25. It appears with quicksilver ores in Almaden (Spain), Hungary and Chile.

H. Discrasite (Antimonial Silver).

Color, silverwhite—if exposed yellowish or greyish; slightly brittle. Specific gravity, 9.4; smelts readily under the blowpipe.

There are besides the ores mentioned, other compositions but too rare to be of interest to the practical miner and we therefore omit them.

We shall now proceed to give an illustration how a practicel miner, with the aid of a blacksmith's fire and a few simple appliances, can make his own *assays of gold and silver ores.*

The only costly appliance required is a scale, which on being loaded with 100 milligrammes would indicate one-tenth of a milligramme. Scales of that description can be purchased for about $75. Besides that there would be necessary a pulp scale at a cost of about $10; some crucibles, test tubes, drying cups and cupels.

To make an assay of a gold or silver ore, pulverize the same finely, weigh off 20 grammes on the pulp scale, and mix the same with five or six times its weight with litharge, add one teaspoonful of soda, a little borax, and a very little pulverized charcoal; mix the whole well and place it in a crucible; cover the mixture with a layer of common salt and put your crucible in the blacksmith fire or; put a cover on it and build a fire all around and over it, then expose the same to bright red heat for about 20 minutes, this will suffice to bring the whole to flow. Now take your crucible, pour quickly into a mould and allow the mass to cool. You can then readily seperete the slag from the metallic bottom, and by hammering it clean it for the second operation, which is the cupelling.

(To be Continued.)

The Silver Question.

In another column we give the full text of the "silver bill," which was passed by Coogress, signed by the President, and is now a law. Still another silver bill has been agreed upon by the Committee on Mines and Mining, which is as follows:

A bill to utilize the product of gold and silver mines and for other purposes:—Be it enacted, etc., that coin notes of the denomination of $50, and multiples thereof up to $10,000, may, in the mode hereinafter provided, be paid by the several mints and assay offices at San Francisco, Carson City, Philadelphia and New York, for net value of gold and silver bullion deposited thereat, and of bullion thus received not less than 75 per cent. in coin or fine bars shall at all times be kept on hand for redemption of coin notes, gold for gold and silver for silver. Gold deposited shall be computed at its coining value, and silver at the rate of 412 8 grains standard silver to the dollar, less lawful mint charges and such charges for transportation from assay offices to mints for coinage, and from the latter to the Assistant Treasurer's respectively, by whom the coin notes shall be payable; and there shall be coined at the mints of the United States the silver dollar hereinbefore mentioned. Third—The Secretary shall from time to time cause coin and fine mint bars stamped to be transferred from the mint to the Assistant Treasurer's at San Francisco and New York in such amounts as may be necessary for redemption of coin notes. Fourth—The coin notes thus issued shall be receivable without limit for all duties of the United States, and the coin mentioned in this act shall be a legal tender for all debts, public and private, not specified to be paid in gold coin. Fifth—Gold notes issued according to this act shall be redeemed on presentation in gold coin or fine bars, and silver in silver dollars or fine bars. Sixth—Coin notes authorized by this act to be issued shall be prepared under direction of the Secretary of the Treasury, and be transferred to the above named mints and assay offices as a part of the bullion fund, and from which fund deposits shall be paid for in coin or in notes, at option of depositors. Seventh—Fine gold or silver bars herein authorized to be issued shall bear the mint stamp of fineness, weight and value, and the value of gold bars be computed according to their coining rate and of silver bars all their coining value in dollars. The Secretary of the Treasury shall prescribe the necessary regulations for carrying the foregoing provisions into effect.

This bill has two features which, should it become a law, will have an important influence on the business of the country. One of these features is, the recognition of two currencies—gold coin and silver coin—whose relative value will be determined by the commercial value of the metal of which they are composed. A second feature is, that the coin issued under this act shall be a legal tender for all debts, public and private, not specified to be paid in gold coin. The practical effect of this bill, if it should become a law, will be to make legal tenders redeemable in silver on the basis of the old silver dollar of 412 8 10 grains. It is provided that bullion, either gold or silver, may be deposited at the several mints and assay offices of the United States, and notes, gold or silver, according to the deposit, be issued of the value of the bullion, less mint charges, in payment therefor. The depositor has the option of payment in coin, and the notes are at all times to be payable in coin. To secure payment, seventy-five per cent. of the bullion received is to be kept on hand, gold notes to be redeemed with gold coin and silver with silver coin.

The tendency of this measure will be to increase the uses of silver, and thus indirectly enhance its value as a commodity.

THE O'HARRA

CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
1500 lbs of salt at 1½c	22.50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

DEETKEN'S

ROASTING FURNACE,

For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 6 to 50 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adapted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

G. F. DEETKEN,
Consulting Metallurgist, Grass Valley, Cal,

Furnace can be seen on application for permit, at Grass Valley.

Marine Screw Engines

And BOILERS for driving Model Yachts from one to ten feet in length, and Row-Boats or Skiffs 16 feet and upwards in length; either plain castings, partly finished, or complete ready for use, so constructed that a speed of from six to twenty miles per hour can be easily obtained.

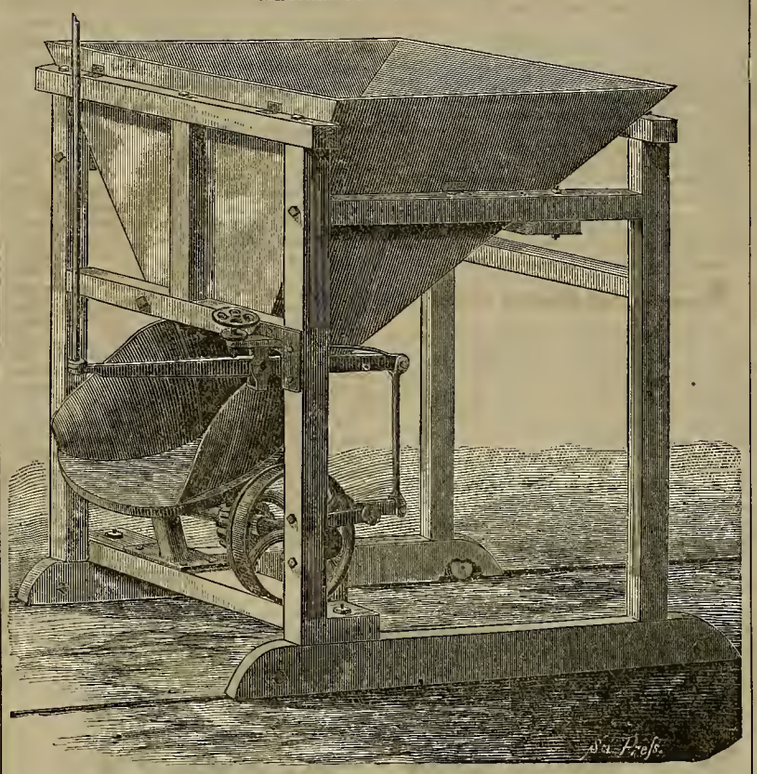
The Engine can be quickly detached from the Yacht or Boat, and is then suitable for Agricultural, Domestic, Mechanical, Commercial or Amateur requirements, when small power only is needed.

☞100 Scroll Work Designs free on receipt of Stamp.
GEO. PARR, Buffalo, N. Y.

HENDY & COCHRANE'S ORE FEEDER

FOR QUARTZ MILLS,

AWARDED FIRST PREMIUM AT THE TENTH INDUSTRIAL FAIR OF THE MECHANICS' INSTITUTE.



It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the *carrier*, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane, or table, to the line of discharge, and there simply *dropped*. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says, of the Table Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."——A letter from Mr. C. O. Belding, of Amador County, speaks in the highest terms of them.——Two of the machines were shipped to the Bunker Hill Mill, Amador County.—— Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen.——Mr. Lachman, of the Soulsby Mill, Tuolumne County, says they work splendid; could not do better.——Two of the machines were shipped to the California Company, Nevada City.—— C. J. Garland, of Mosquito Gulch, Calaveras County, says: "I find them an excellent machine."——S. D. B. Stewart, Supt. Lincoln Gold Mining Company, says they are a perfect success.——O. C. Hewitt, Supt. Keystone Mining Company, says: "I can safely recommend them to all millmen."

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other machine of its class.

THE BUCKMINSTER ROCK DRILL.

The Most Efficient Rock Drill in the Market.

LIGHT, STRONG and DURABLE.

No External Machinery Liable to Injury from Rough Usage, as all the Working Parts are Enclosed in the Cylinder and Valve Chest.

A TRUE SMOOTH HOLE EVERY TIME. THE MOST ECONOMICAL DRILL YET MADE.

THE WORKING PARTS OF THE DRILL ARE FEW AND SIMPLE IN ARRANGEMENT, SO THERE IS NO LIABILITY OF INJURY. THE CLAMPS FOR HOLDING THE DRILL ON THE TRIPOD, FOR HOLDING THE DRILL TOOL IN POSITION, AND FOR FIXING THE WEIGHTS ON THE LEGS OF TRIPOD, ARE ALL IMPROVED AND VERY EFFECTIVE.

The device for rotating this Drill has few parts, and can not get out of order. There is no chance for wear. The motion is positive, and never fails of action. The Drill Carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp.

All parts subject to wear are of the Best Cast Steel, and all made to gauge and interchangeable.

This is the Lightest and Strongest Rock Drill yet invented. Being nearly all Cast Steel, it is easily handled and moved, as all superfluous metal is dispensed with.

We also call the attention of those interested to the Horizontal Air Compressor furnished with the Buckminster Drill when desired. It is Economical, Light, Easily Run and conveniently portable.

We claim that the Buckminster Drill will do as good work as any in the market, at a much less expenditure of power, and a great decrease in first cost of machinery. Drills made all the usual sizes.

Mining Companies Desiring Rock Drilling Machinery should Examine this Drill and Air Compressor, and we are confident that it will give satisfaction. Address,

PACIFIC IRON WORKS,

FIRST & FREMONT STS., NEAR HOWARD, S. F.

MANUFACTURERS OF ALL CLASSES OF MACHINERY.

BLACK DIAMOND FILE WORKS.

G. & H. BARNETT,
Manufacturers of Files of every Description
Nos. 39, 41 and 43 Richmond street,
Philadelphia, Pa.

Sold by all the principal hardware stores on the Pacific Coast. LINFORTH, KELLOGG & CO., General Agents for the Pacific Coast.

San Francisco Pioneer Screen Works,
J. W QUICK, MANUFACTURER,
32 Fremont Street, San Francisco.

SCREENS

Several first premiums received for quartz mill Screens, and perforated sheet metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill Owners using battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

IRON PIPE.

Having been appointed Agents for the Washington Pipe Works, we are prepared to ship from store, Pipe and Fittings at the lowest market prices.

BERRY & PLACE., San Francisco.
TREADWELL'S OLD STAND.

Gloves Made to Order

At prices most economical to customers, at the SACRAMENTO GLOVE FACTORY of I. W. Lusk, Tenth St., between J and K Sts., Sacramento. None but the best quality of California tanned skins used. Ladies' and Gents' colored plain and Indian dressed riding and common gloves and mittens on hand, or made to order on short notice. ☞Send your size or number and you can order by mail. Satisfaction guaranteed. Ladies, farmers, miners, engineers, and all requiring serviceable gloves are invited to call at the factory.

ERICH G. GAERTNER,
MINING ENGINEER.

All classes of mining properties reported on, consultations had on reduction of ores of all descriptions, plans for furnaces and reduction works furnished, and the construction of them superintended. Ore tests made at the office,

309 California street, Rooms 8 and 9.

A Desirable Bargain.

Mr. Lee H. Utt, of Pala, San Diego county, offers for sale a share in his valuable place, consisting of 320 acres, and situated as described above. There is an Apiary on the ranch in successful operation. For this business it possesses marked advantages. Twenty acres are seeded to alfalfa and eight acres are in vines. The place has growing on it 420 trees, many of them in bearing.

The owner will warrant the Cavendish Dwarf Banana to grow as well here as in Florida. He has three now growing. The pasture now enclosed will keep 50 head of cattle. The ditch—which is large enough to run a mill—is stocked with trout, and has a fish pond 100 feet square, and full of fish. There is a nice warm spring, with bath house; the water contains sulphur, salts and iron.

The place possesses great natural advantages, and the present owner has not spared money nor labor to improve; but being a valetudinarian he is not strong enough to attend to the work. To the right kind of a man a rare opportunity is here offered. To such a person as will come in good faith he extends the invitation to stop on the ranch long enough to become familiar with its characteristics and capacities.

Parties can refer to I. Nast, stock broker, San Francisco, or to anybody of note in San Diego. The place bears the name of "Aqua Tibia." Address,

LEE H. UTT,
Pala, San Diego County, Cal.

JOHN LUTTRELL MURPHY,
Attorney and Counsellor at Law,
NO. 535 CLAY STREET,
SAN FRANCISCO.

F. MANSELL & CO.,
SIGN PAINTERS,
423 PINE STREET,
(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors,	Gents' Furnish'g G'ds
Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotels,	Piano Fortes,

Wine Merchants, Etc., Etc.

Continued from Page 78.

Idaho.

Mr. Baldwin Free.—Idaho *Avalanche*, July 22: The miners and citizens of Fairview showed a commendable spirit at their meeting on Friday morning, over which Thos. Ellis presided, in unanimously deciding to release Mr. Baldwin and give him an opportunity to go to San Francisco and represent how matters stood here. The best of feeling prevailed all round. Mr. Baldwin authorized his clerk in his absence from town to sign checks and draw orders for such goods and provisions as the men might need previous to his return.

South Mountain.—Notwithstanding this camp has been partly deserted of late, favorable reports have just come to hand pertaining to the resumption of operations. A movement combining the needed capital has probably been consummated with that view. There is plenty of ore in that camp to be reduced, and in a month or six weeks from the present time it is quite likely that the furnaces will be in operation.

The South Chariot.—L. P. Goldstone, of San Francisco, arrived here recently to take the management of the South Chariot mill. The company's indebtedness is being rapidly paid off, and it is reported that work will be resumed in the mine some time during the month of August.

Montana.

Mining Items.—Helena *Independent*, July 18: Mining about Cave gulch is turning out better than the prospects promised early in the season. Mining in Montana gulch is being prosecuted with vigor. A large force of hands will be at work on the Rumley mine in a few days. The placer mines at Bannack are furnishing a fine supply of gold. Several rich discoveries have recently been made in the Trapper district. Several placer claims have been purchased by Chinese in Emigrant gulch. Eighty-four tons of ore from the Acquisition Spur lode, at Butte, have been shipped East for reduction. Copper ore from the Park mines is going forward to Salt Lake for smelting. Three shafts have been sunk on the Trevonia lode—one of them is to a depth of 70 feet. A splendid nugget, assaying $145, arrived yesterday from the Snow Shoe mines. Twenty thousand dollars in gold dust was sold in Helena Monday, and $21,000 on Wednesday. Twenty-two tons of second grade ore from the late Acquisition Spur lode sampled $400 to the ton. A streak of $500 ore has been found on the Clear Grit lode near Butte. A fine clean-up was made last week on El Dorado bar. The mines in Hendereon gulch are being worked with fine results. There is plenty of water to work the Nevada creek mines. Miners on Spruce bar are taking out good pay. Several new mining claims are being worked on Boulder bar. The Rochester mill is working rich ore and makes a fine showing in silver bullion. The Willow creek mines are turning out well.

Oregon.

Prospecting.—Oregon *Sentinel*, July 19: Parties are already beginning to go out prospecting. Already several are far among the hills, and in a short time many more will be on the way. Recent discoveries in the "gravel range" have given new impetus to the search for deep placers, and before long we expect to hear of some big strikes.

A Mica Lead.—Taking a hint from a paragraph published in this paper a few weeks ago, a party began to look up mica, or isinglass, mines around in this vicinity. On Saturday last Mr. J. P. Blaylock brought in some specimens of mica from a ledge found about 25 miles northeast from here, which were the finest we have seen. They were picked from the surface, on or near a ledge of large size, are more or less mixed with quartz and have been discolored and fractured by the action of the elements. Flakes or sheets of from one to two inches in width by two or three inches in length are obtained from the specimens shown to us. The discoverers intend developing the ledge soon, and are confident of finding an endless supply of marketable quality.

Utah.

Beaver District.—Cor Salt Lake *Tribune:* The Cave mine, in Bradshaw district, has struck four feet of high grade milling ore in the incline, with an average assay of $300 per ton. This mine has improved wonderfully in the last 60 days in the value and extent of ore. The mine is shipping considerable ore daily to the Shaunlie smelter, which works high in silver and gold.

Lincoln District.—The Rollius mine is said to have been purchased by Angle & Co., of Chicago, at a fair figure, and it is rumored that work will soon be commenced again on the mine. It has been a prominent piece of property, but has been delayed considerably by being troubled with water. There is, however, considerable ore in sight in the deepest works.

The Coral Reef mine is situated in the above district, and is looking well. It is showing a large body of high grade ore in its works, and the owners are confident of developing a second bonanza.

The Shauntie smelter is still on Pioche and Star ores, and is making a successful run, turning out considerable bullion every 24 hours. Mr. Shinmar has gone to Bristol to select a site for the purpose of putting up a smelter in that section of the country to work Pioche and Bristol ores. Shumar & Co. are the only go-ahead smelters who have met with success in Southern Utah, and who are fully competent in the smelting line. The strike in the Savage mine, in Star district, creates considerable excitement in mining circles. It is developing in extent and value. The San Francisco smelter shut down last week for repairs, after a successful run of 10 days under the management of Chris Heinecke, on Big Bonanza, Dykes and Rebel ores, and turning out 50 tons of bullion. The smelter will start up as soon as repaired, and I am informed it is the intention of the Bonanza owners to put up another stack.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

North Prospect M. Co.—July 15th. Location: Nevada. Directors—F. D. Atherton, H. M. Newhall, P. N. Lilienthal, B. Flint and F. A. Benjamin. Capital, $10,000,000.

Great Eastern Gravel M. Co.—July 15th. Location: California. Directors—Hugh Greenless, Mathew Mane, Samuel W. Moore, James McCloskey and Wm. Small. Capital, $1,400,000.

Charlotte G. & S. M. Co.—July 15th. Location: Inyo Co., Cal. Directors—Charles G. Ewing, James P. Colp, David Samuels, J. L. Armstrong and S. F. Walsh. Capital, $10,000,000.

Mariposa Con. G. M. Co.—July 15th. Location: Mariposa Co., Cal. Directors—George Peters, Theo. F. Tracy, Robert C'Neill, A. Bateman and Wm. T. Reynolds. Capital, $66,600,000.

Gould & Barnhart S. M. Co.—July 18th. Location: Nevada. Directors—Joshua I. Ayres, P. D. Barnhart, George L. Woods, Joshua Hunt and J. B. Crosby. Capital, $100,000.

Avery & Crosby S. M. Co.—July 18th. Location: Nevada. Directors—Joshua L. Ayres, P. D. Barnhart, George L. Woods, A. S. Gould and J. B. Crosby. Capital, $100,000.

Union Petroleum Co.—July 15th. Object: To bore and dig for oil in Los Angeles county. Directors—T. L. M. Chipley, Wm. Parsons, F. A. Berlin, George S. Riggs and John A. White.

Newhall Petroleum Co.—July 15th. Object: To bore for oil in Los Angeles county. Directors—T. L. M. Chipley, Wm. Parsons, F. A. Berlin, George S. Riggs and Thos. C. Huxley.

Shasta Coal Co.—July 19th. Directors—H. H. Haight, S. J. Kellogg, Joseph Warethman, Wm. S. St. Anburn and M. H. Peck. Capital, $5,000,000.

Spanish G. M. Co.—July 19th. Location: Nevada Co., Cal. Directors—Erastus Bond, James Shorkley, S. P. Lord, A. R. Lord and H. H. McClellan. Capital, $5,000,000.

Lone G. & S. M. Co.—July 20th. Location: Nevada. Capital stock, $10,000,000. Directors—Geo. Muck, John Bruner, Henry N. Stahl, Al Peck and E. A. Peck.

Aptos Water Co.—Capital stock, $500,000. Object: To supply the towns of Aptos and Soquel, in the county of Santa Cruz, with water taken from the Aptos and Valencia creeks. Directors—Claus Spreckels, G. A. Haas, M. Rosenbaum, G. H. Eggers and J. Brandenstein.

Custer G. M. Co.—July 24th. Location, Mariposa county, Cal. Capital stock, $3,000,000, in 30,000 shares of $100 each. Directors—H. G. Rollins, San Francisco; L. A. Booth, Oakland; Fred Homer, T. G. McLenan, S. N. Putnam, San Francisco.

Manhattan Ore Treating Co.—July 26th. Capital stock, $5,000,000. Object: Manufacturing and selling of machinery, treating gold and silver ores, etc. Directors—Chas. F. Secor, A. C. Bradford, Chas. Chandler, James H. Smith and O. D. Squire.

Meetings and Elections.

Phil Sheridan M. Co.—July 24th. Trustees—J. A. Pritchard (President), J. J. Scoville, (Vice-President), George Townsend, Joseph McGillvray and S. A. Raymond. W. R. Townsend was elected Secretary, and the London and San Francisco bank Treasurer, and Sam'l L. Jones Superintendent. There were 16,260 shares represented. The company has recently erected fine hoisting works, and rapid progress is being made in sinking. The Secretary's statement shows $6,750 in the treasury, with outstanding liabilities of $6,000.

Proto M. Co.—July 22. Directors—H. H. Flagg, J. P. Forbes and A. P. Forbes.

Savage M. Co.—Samuel T. Curtis has been elected Superintendent in place of F. F. Osbiston.

Emigrant S. M. Co.—July 26th. Directors—Maurice Dore, Stephen H. Phillips, B. W. Mudge, Philip Falk and J. E. Shawhan.

Patents & Inventions.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

From Official Reports for the Mining and Scientific Press, Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

For Week Ending July 18th, 1876.

Hampton Kelley, Multnomah, Ogn., fruit drier; James McAllister, Gold Hill, Nev., casting car wheels; Benj. F. Penniman, S. F., purifying and amalgamating gold and silver bearing sand, etc.

Reissues.

John S. Hall, S. F., assignor to John L. Boone, short thread sewing machines; Redmond Gibbons, S. F., adjustable elastic straps for garments.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Coffins.—Wm. O'Day, S. F. The object of this invention is to cheapen the manufacture of wooden coffins by providing a simple and convenient method of constructing and applying the ends of that class of coffins or caskets which is made with octagonal ends. Ordinarily each piece which is used in the formation of the octagonal ends is cut and fitted separately so that it requires much labor and nice workmanship to properly construct a coffin. This is owing to the number of miter joints to be fitted and the taper of the casket, which necessitates each piece to be tapered and fitted correspondingly. By this invention an octagonal form of any given length is first constructed, either tapering or otherwise, according to the shape of the coffins to be made. This form is made of the proper size to serve as a pattern upon which to fit and put together in long strips the boards which are to form the ends of the coffins. The inventor then takes the long boards and miters, fits and nails them together so as to provide an octagonal end piece of any desired length, which can be cut into short lengths to form the ends after they have been fitted to the body of the coffin. By this arrangement the long end pieces can be put together at a mill cheaply, and as the pieces are put together on a form no mistake can happen. The work is therefore done more cheaply, and all that the coffin maker has to do is to construct the box or body of his coffin to conform to the ends and then put them together, thus enabling him to produce a cheaper and at the same time a neater coffin than when the pieces have to be fitted singly. The arrangement also enables the maker to construct the coffin out of boards which have been stained and polished in the long piece before they are cut up.

Barrel Tap and Faucet.—Elisha T. Barlow, S. F. This invention relates to that class of permanent taps for beer and other barrels in which the valve admitting the liquid to the faucet is arranged on the tap, and is operated by an independent key or implement after the faucet or tube through which the liquid is drawn has been secured in place on the tap. The inventor produces a combined tap and faucet that can be cheaply manufactured and which is not likely to get out of order. A common bent tube can be used instead of a faucet, and will serve every purpose as a conductor of the liquid.

Mining Accidents.

Several serious accidents have happened in the mines this week, the most disastrous of which was one which occurred to gang No. 3 of the Black Diamond coal company's works, Nortonville, Contra Costa county. It was at first stated that the explosion was caused by the ignition of the dry coal dust that had accumulated in the chutes, cross-cuts, breasts and gangways, from a blast fired in one of the breasts. It transpires, however, that although the primary cause of the disaster was the ignition of a quantity of coal dust, the greatest evil was done by the explosion of a twenty-five pound keg of blasting powder, with which the fire communicated. Eight men in all were killed, six on the spot and two afterwards. Their names were: William Gaethee, William L Williams, Meredith Lewis, George M. Reynolds, David Griffith, David W. Griffith, Theophilus Watts and T. Dumas. Dangerously burned, Thomas D. Davis, David Watts and Evan Smith. Slightly burned and recovery probable: Thomas D. James, Harry Manwaring, Giacomo Larggo; and Watkin Williams, asphyxiated, will probably recover.

The damage to the mine was not of a serious nature. Though there was some trouble in getting the men out on account of some slight caves, no interruption to the mining work was incurred. The accident occurred in the 400-foot level, the lowermost of the workings, in what are called the new openings. A quantity of coal dust had ignited, and the supposition is that a keg of blasting powder, containing 25 pounds, became ignited by the fire. The men killed were near the spot, but did not lose their lives simply and immediately by the force of the explosion, but from asphyxia; the condition of four out of the five showing clearly that this was the case. There were no marks of violence on any of the bodies.

In cases of asphyxia very much depends on the length of time which elapses before the sufferers have assistance, and no doubt if, as stated, the men were simply asphyxiated, not hurt by the powder explosion, if they could have been immediately removed they could have been brought to. The usual remedy in such cases is to produce artificial respiration, as in the case of partially drowned persons. By forcing the deleterious gas from the lungs and blowing in pure air respiration is induced, and if not too late the patient can be restored. As to the means of entering places rendered dangerous by bad gas, some remarks are made in another column of this issue.

A terrible storm visited Gold Hill, Nev., on the 22d inst., exceeding any in severity experienced in many years. It partook more of the nature of a cloud burst than anything else. At the time of the cloud burst a fatal accident occurred at the Lady Washington mine. The flood of water rushing down Gold canyon was so great that it backed up into the drain tunnel from the shaft to the ravine. There being probably but about one foot of fall in the whole length of the drain tunnel, and the rise of water being two or three feet, a perfect deluge of water was suddenly poured down into the main shaft where four men were at work. The men rang the bell for the cage to be lowered, and when it came down two of the men got on board of it and went to the surface. Why the other men did not get upon the cage does not very clearly appear, as we are only told that they were "too slow." Being left in the shaft and finding the water pouring in upon and rising about them, they began climbing up the timbers of the shaft. Those above lowered the cage again with a man aboard who had volunteered to go down. When he had descended about 40 feet below where the drain tunnel connected with the shaft, he found the flood of water pouring down so great that he was in danger of being drowned on the cage, and so was obliged to ring to be brought back to the surface. After the rush of water was over the cage was again lowered and one of the men was found safe in the pump-station at the 700-foot level, to which he had climbed. The other man, Thomas Ryan, was not found for some time after, when the shaft had been pumped out, when his dead body was recovered. The shaft was filled to the depth of 80 feet in a short time, so great was the volume of water that poured into it. When Ryan's body was recovered the only mark found upon it was a cut on the back part of the head. The wound was not of such a nature as to have caused death, therefore the unfortunate man must have drowned. It is thought that in trying to climb up the timbers of the shaft he lost his hold and fell back into the water, his head striking a timber in his fall.

On the 14th inst. a man working in the Yellow Jacket mine, on the Comstock, met with a curious accident. The *News* says: He was engaged with other workmen in retimbering the west compartment of the shaft, and was about 50 feet below the 1100-foot station. In his work it became necessary to take out a guide bolt from the guides, and in doing so he put a two-by-six inch plank across the shaft to stand on. The pump-man in the next compartment had started to go down, and Richards thought he would have time to get his job finished before the cage in his compartment came down again. The two cages are so joined that when one goes down the other comes up. After going down a little more than 100 feet, the pump-man rang his cage to the top again. This sent the cage down into the compartment where the workingmen were, and before Richards was fully aware of his situation he was caught between the descending cage and the plank on which he was standing. The motion of the cage was fortunately slow and the weight of it was put upon the plank by degrees.

The tank was also on the cage, and the combined weight was so great that the plank was broken, Richards being literally mashed through it. He fell a distance of more than 50 feet, to the bottom of the shaft. There was about 15 feet of water in the sump, and to this fact may be ascribed the escape of Richards from death. He was picked up out of the water, in a few minutes, in an insensible condition. Upon examination it was found that no bones were broken, but that Richard's entire left side was badly bruised and crushed.

Foundry Work.

The Etna Iron Works.

The press of work at the foundries for the season is over and comparative dullness now prevails. More or less general work is of course on hand at all of them, but they are by no means busy.

At the Etna foundry they are working a full complement—from 70 to 75 men. The largest work at present on hand is an engine for a saw mill of Dolbear & Carson. This is a 14x30 engine designed especially for them. It has glass gibs in the cross-heads and is supplied with both the Saunders and Dunbar patent steam piston packing. Saunders' metallic packing has been in use at the Ætna works for a year or more and is found to answer the purpose admirably, being very tight and at the same time causing no heating.

They are also making an 8x16 engine for a mine in Mexico. This is built in sections so as to be packed on mule back to the mine. The heaviest piece weighs 350 pounds. They are also making the castings for a set of Secor's amalgamating machinery.

They are engaged also on castings for Smith's three cylinder pumps, of the pattern recently described and illustrated in the Press. One of these is a seven-inch pump for the Coquille Black Sand mining company. The demand for these pumps is increasing. The principle is to keep the column of water continually moving without stoppage such as occurs in the ordinary pump on the return stroke.

At this foundry castings are being made of slag pots, lead molds and smelting work machinery for the reduction works in Oakland. Considerable work of the same kind is also being done for the New England smelting and tunnel company, Tulare county, and the works of the Defiance company in Inyo county.

One of O'Hara's roasting furnaces, recently described in the Press, is being made for the Exchequer mine. Work has just commenced on a White roasting furnace for a mining company at La Paz. Considerable jobbing work is being done also; in fact, the principal part of the business of this foundry is of this class. They are at present putting in six sidewalk hoists at Baldwin's building on Market street, and doing other work of a similar character.

General News Items.

The Custer fund amounts to $40,000.

There are 88 miles of good street sewers in San Francisco.

A general reduction of wages is imminent in Glasgow.

The Sultan of Turkey is suffering from delirium tremens.

According to the dispatches the atrocities in Bulgaria still continue.

The Frear stone works in this city were destroyed by fire on Sunday.

Dispatches received state that General Canal has been elected President of Hayti.

Forty of the crew of the *Thunderer* were killed by the recent explosion, or have died from the effects of it.

The fast mail train between New York and the West was discontinued on the 22d, the House having reduced the appropriations for the postal service so greatly that it could not be maintained.

All children attending the public schools are now required to present to the teachers of the classes to which they belong a physician's certificate showing that they have been vaccinated within seven years.

The yacht *Mohawk* was capsized by a squall in New York harbor on the 19th inst., and Commodore Garner, of the New York yacht club, together with his wife, Miss Adele Hunter, Frost Thorne and the cabin boy were drowned. The accident is attributed to the carelessness of Captain Rawlings, the sailing master.

A material for packing stuffing boxes recently patented in England consists in thin pliable shavings of soft metal or alloy, such as is employed to form soft metal bearings.

Information is wanted at this office of Mr. J. M. McArthur, who was last heard from June 29th, at San Bernardino. Said he was bound for Panamint.

Woodward's Gardens embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

The Mechanics' Fair Daily.

This journal, printed and issued in the Pavilion of the ELEVENTH INDUSTRIAL EXHIBITION, and circulated free, will be a superior publication. It will contain all OFFICIAL INFORMATION during the Exhibition, commencing Aug. 8th, 1876 ITS ILLUSTRATIONS will furnish accurate views of NEW INVENTIONS AND MACHINERY.

The volume will give a substantial and readable RECORD OF THE FAIR, quite valuable for reference and preservation, in addition to a goodly variety of other reading matter, daily, embracing GRAPHIC PARAGRAPHS AND HUMOROUS INCIDENTS, making altogether a paper eagerly sought for (both in and out of the Pavilion) by nearly a QUARTER OF A MILLION OF READERS during the term of the Exhibition—a circulation reaching a greater number of different individuals than that of any publication yet issued.

We shall make a specialty of inserting ATTRACTIVE ADVERTISEMENTS, representing the leading firms in nearly EVERY BRANCH OF TRADE AND INDUSTRY on this coast, upon favorable terms, soliciting such as we believe will be most benefited by advertising in a well conducted, enterprising and everywise meritorious journal.

This beautifully illustrated sheet, issued upon such an occasion, will receive close attention, and its contents—both reading and advertising being original—will be closely scanced throughout.

THE IMMENSE PAVILION has been improved for the coming Fair. An unusually large amount of space for exhibits has already been engaged. Special exhibitions and new and attractive features will be introduced, calculated to make the Fair of 1876 a GRAND SUCCESS.

Orders for advertising, sent in early, will receive careful attention.

The undersigned, publishers of the MINING AND SCIENTIFIC PRESS, have successfully issued a popular daily in the Mechanics' Fair during seven Industrial Exhibitions since 1864, and we are now confident of making the coming volume surpass all its predecessors in its standard of value as a reading journal of art and information and a medium of first-class business announcements.

We have been awarded by the managers of the Exhibition the EXCLUSIVE PUBLISHING AND ADVERTISING PRIVILEGES of the Eleventh Industrial Exhibition, and are determined to accomplish a work creditable to the MECHANICS' INSTITUTE, to OUR PATRONS AND TO OURSELVES.

DEWEY & CO.,

Publishers and Patent Agents, No. 224 Sansome street, S. E. Cor. of California, S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

"Faith and Confidence"

LIVERMORE, Oct. 1st, 1875.

MESSRS. DEWEY & CO., Patent Solicitors: *Gentlemen*—Yours of the 29th ult. containing my patent to Elevated R. R. duly received, and I hereby return my sincere thanks to the MINING AND SCIENTIFIC PRESS Patent Agency for your promptness and honesty in regard to our business connections. I have received a flood of circulars from Eastern firms, desiring to deal with me, but I have declined any communication with them and prefer, as soon as circumstances will permit, to negotiate with and patronize a home institution; one in which I have faith and confidence—DEWEY & CO.

Again thanking you for your promptness in securing my patent, I remain, obediently yours,

WM. H. HARRISON.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867. The most complete treatise. Published at this office. Price $5. Postage, 50 cts. extra

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver. 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price $2.50 coin, or $3 currency, postage free. Published and sold at this office.

CHOICE VOLUMES.—We have a full new set of *Scribner's Monthly*—ten volumes—well bound, for sale at this office. Price, $2 per volume.

SEWING MACHINES.—We have a first-class machine we wish to dispose of on favorable terms. Apply at his office.

Mining and Scientific Press,

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Millman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns for fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,

No. 224 Sansome street, S. F.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address,

DEWEY & CO.,

Publishers MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, San Francisco.

THANKS, ETC.—*Messrs. Dewey & Co.—Gents:* I write to acknowledge the receipt of letters patent on my fruit drier, which came to hand to-day. Accept my thanks for the very satisfactory and successful manner in which the case has been handled.

Respectfully yours, HILAND G. HULBURD.

Placerville, July 20th, 1875

To Mining Secretaries.

An emendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for service personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Antilles Mining Company—Location of

principal place of business, San Francisco, Cal.

Notice is hereby given, that at a meeting of the Directors, held the seventh day of July, 1876, an assessment of 20 cents per share was levied upon the capital stock of the corporation, payable immediately, in U. S. gold coin, to the Secretary, at his office, No. 207 Sansome street (third floor), San Francisco.

Any stock upon which this assessment shall remain unpaid on August 16th, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, September 8th, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

H. M. MORGAN, Secretary.

Office, 207 Sansome street, San Francisco, Cal.

Cherokee Flat Blue Gravel Company—

Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment, No. 36, levied on the eighth day of June, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
A Uasell	17	4603	$230 40
Mrs Mary W Farrington	35	144	7 20
Mrs E M Walton, balance of certificate No. 21 128 shares sold for assessment No. 35	81	73	3 65
George W Remage, balance certificate No. 36. 320 shares sold for assessment No. 35	83	235	11 75

And in accordance with law, and an order of the Board of Directors, made on the eighth day of June, 1876, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, room 13, No. 328 Montgomery street, San Francisco, Cal., on Saturday, the fifth day of August, 1876, at the hour of two o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

O. H. BOGART, Secretary.

Office, Room 13, Safe Deposit Building, San Francisco, Cal.

Office South Comstock Gold and Silver Mining Company.

NOTICE.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of trustees and the transaction of such other business as may be presented, will be held on Monday, the 21st day of August, 1876, at two o'clock P. M., of that day, at the office of the company. Transfer books will be closed on Wednesday, August 16th, 1876, at three o'clock P. M.

J. M. BUFFINGTON, Secretary.

Office, Rooms 3 and 4, No. 311 California street, over Ætna Insurance Office, entrance 309 California street, San Francisco, Cal.

Kearsarge Consolidated Quicksilver Mining Company.

Principal places of business, San Francisco, Cal. Location of works, Lake Mining District, Lake County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the first day of July, 1876, an assessment of fifteen cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, No. 10 Stevenson Block, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 28th day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 16th day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale

JAMES MCHAFFEE, Secretary.

Office, Room 10, Stevenson Block, San Francisco, Cal.

Mariposa Land and Mining Company

of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixth day of July, 1876, an assessment (No. 6) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 9 Nassau street, New York.

Any stock upon which this assessment shall remain unpaid on the seventh day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the second day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Office of the Tintic Milling and Mining Company,

San Francisco, Cal., July 14th, 1876. The annual meeting of the stockholders of the Tintic Milling and Mining Company will be held at the office of the company, No. 310 Sansome street, San Francisco, on Monday, August 14th, 1876, at two o'clock P. M., for the election of directors for the ensuing year, and the transaction of such other business as may be brought before the stockholders. By direction of the Board of Directors. H. CLAY MILLER, Secretary.

San Francisco, July 14th, 1876.

Umpire Tunnel and Mining Company—

Location of principal place of business, San Francisco, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No 5), levied on the 23d day of June, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, AUGUST 5, 1876.

VOLUME XXXIII Number 6.

A Geological Anomaly.

A Noted Calcareous Deposit—One of Lyon County's Industries.

A short time ago your correspondent had the pleasure of visiting the Dayton lime works, owned by, and under the immediate supervision of Mr. H. C. Blanchard, an old and popularly known resident of Nevada. The works are situated about two miles southeast of the town of Dayton and about the same distance, in an easterly direction, from the Carson river, at the base of the Como range of mountains, near the mouth of a long, deep canyon or gorge known as El Dorado canyon.

The Location of the Deposit,

As well as the surrounding country is most singular, being pronounced by Professor Stewart to be a "geological anomaly," as the formation of the same, is such that the existence of limestone, even in small quantities, is as curious and unexpected as many other characteristics which it possesses. Before proceeding further I will state that the quotations used referring to its geological structure are taken from a report lately made for Mr. Blanchard, by the well known geologist and mineralogist, Professor W. Frank Stewart, as also the accompanying diagram of the works made by that gentleman. In referring to this singular formation the Professor says: "Owing to the tremendous and wide spread volcanic activities which prevailed in the great American basin during the azoic as well as in more recent periods, the geological structure of Nevada is in many respects, quite anomalous, and geologists are continually surprised and perplexed by the singular juxtaposition and entanglement of tertiary and secondary strata with the ancient hypogene and metamorphic rocks. In many portions of the State we find tertiary beds and carboniferous deposits resting in the very heart of volcanic basins, the former in such close proximity as to warrant the conclusion that either all of the intervening formations, from the subcarboniferous to the miocene tertiary have been entirely obliterated by erosion, or that a marvelous geological hiatus occurred and no such sedimentary deposits ever existed in these localities. A striking example of this unconformability of the geological period occurs at the western base of the Como range of mountains, at a point two miles east of the town of Dayton. * * * * * From exposed and extremely distinct surface indications, a vertical section at this point would give us the following

Series of Strata

Upon a rising scale, first—a bed of homogeneous grey trachyte; second—alternating strata of calcareous slates, argillaceous slates and ferrous oxides; third—compact mountain limestone and gray marble, both impregnated with iron and silver; fourth—a deep stratum of loadstone or granwacke; fifth—a well defined stratum of carbonate of lime, having a vertical thickness of from 12 to 15 feet; sixth—a deep layer of indurated siliceous tufa; seventh, and last of all, a bed of gray pulverent tufa with tertiary sand and soil containing organic vestiges." In the immediate vicinity are found large quantities of ribbon or moss agates; the silicified branches, stumps and trunks of trees; "stranger than all, the surroundings of these petrified relics furnish undubitable evidence that the primeval forest was in existence ages before the awful convulsion, during which the trachyte crown by Mount Como was lifted to the clouds. That the elevation of the mountain was subsequent to the time of those leaf-shedding trees is manifest from the lateral distortion of the stratified rocks; from the westerly bedding of the limestone and loadstone layers." As already noted in item "fifth" of our geological section, this stratum of limestone is perfectly formed, and rests directly upon a permanent bed of loadstone or granwacke. "As this limestone is apparently devoid of organic remains, and as there seems to be no analogous deposit anywhere else in this region, the underlying granwacke with its accompanying argillaceous and calcareous slates, evidently places its origin in the upper devonian or old red sandstone period. At present, what remains of this limestone layer merely serves as crowns for two conical buttes, or eroded nodules of granwacke, and although these

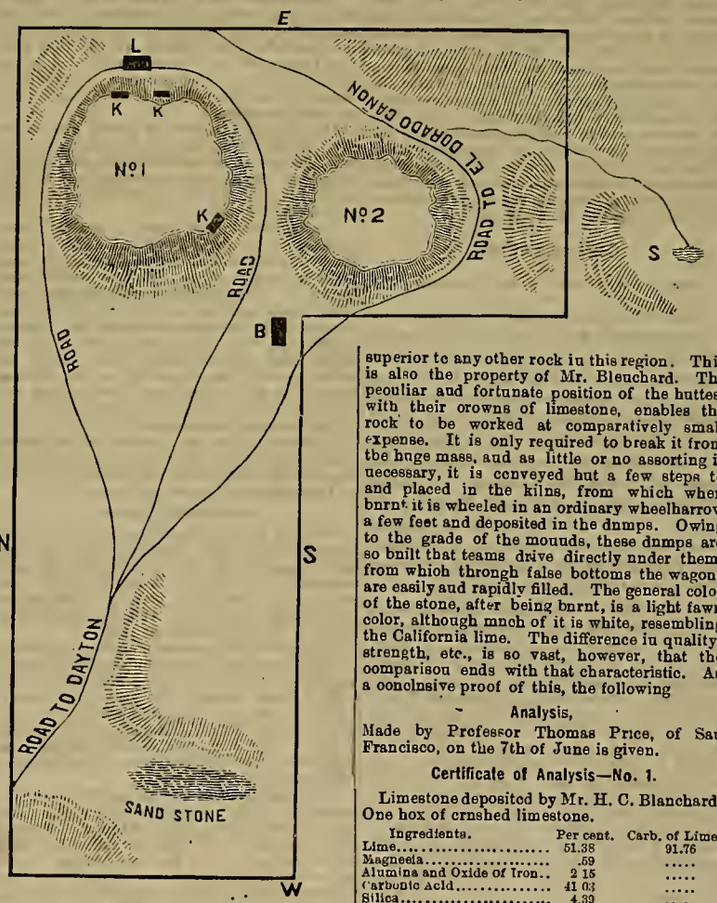
Two Isolated Masses

Of limestone are perfectly conformable with each other, and both occupy their original horizontal positions, yet a slight northwesterly dip of the granwacke bed, together with neighboring rock displacements, plainly indicate that the limestones were bodily elevated from their former horizon when the great trachyte ridge to the eastward arose from the depths."

The accompanying diagram shows

The Relative Positions

Of the two knolls or buttes on the summits of which the great stratum of limestone exists. A small ravine divides them, and they are



LIME WORKS IN EL DORADO CANON.

nearly circular in form, having an elevation above the ravine, from base to summit, of about 50 feet on the southeast, or upper side of the mounds, and probably 60 feet on the lower or opposite side. The lime stratum of butte No. 1, in surface diameter is 290 feet from north to south, and 490 from east to west. That on No. 2 is 290 feet from north to south and 200 feet from east to west, and resembles in appearance the huge croppings or mineral bearing veins such as are often seen in this country. The location is recent, and although

A Large Quantity of Lime

Has already been burnt, sufficient progress has not been made to determine its extent regarding depth; but the geological formation is sufficient to guarantee almost an unlimited amount. This has reference to butte 1, No. 2 having so far remained untouched as regards practical work, while the dimensions given above referring entirely to the visible extent of the stratum, makes in view 530 feet north and south, and 690 feet east and west of the finest possible limestone. Mr. Blanchard was not slow to realize the great pecuniary benefit which might be derived from a proper working of the quarries, and from the period that it passed into his hands to the present, has been constantly adding to it value in way of substantial improvements. He has

Three Kilns,

Which burn on an average 90 tons per week. In this connection we will state that the stone with which the kilns are built, is obtained from a bluff of silicious tufa or sandstone situated but a short distance west of the quarries, and makes one of the finest firestones we ever saw, the intense heat causing it to yield a fine glazed finish or glass coating all over the interior of the kilns. It also makes durable building material having been extensively used in Dayton and Silver City for that purpose, and is considered superior to any other rock in this region. This is also the property of Mr. Blanchard. The peculiar and fortunate position of the buttes' with their crowns of limestone, enables the rock to be worked at comparatively small expense. It is only required to break it from the huge mass, and as little or no assorting is necessary, it is conveyed but a few steps to and placed in the kilns, from which when burnt it is wheeled in an ordinary wheelbarrow a few feet and deposited in the dumps. Owing to the grade of the mounds, these dumps are so built that teams drive directly under them, from which through false bottoms the wagons are easily and rapidly filled. The general color of the stone, after being burnt, is a light fawn color, although much of it is white, resembling the California lime. The difference in quality, strength, etc., is so vast, however, that the comparison ends with that characteristic. As a conclusive proof of this, the following

Analysis,

Made by Professor Thomas Price, of San Francisco, on the 7th of June is given.

Certificate of Analysis—No. 1.

Limestone deposited by Mr. H. C. Blanchard. One box of crushed limestone.

Ingredients.	Per cent.	Carb. of Lime.
Lime	51.38	91.76
Magnesia	.59	.....
Alumina and Oxide of Iron	2.15	.....
Carbonic Acid	41.03	.....
Silica	4.39	.....
Water	.46	.....
	100.00	91.76

This sample was taken from butte No. 1, (which in quality is equaled by No. 2). The only care being exercised was that a fraction should be gathered from every portion of the lime stratum, without regard to its appearance or supposed quality. In reference to which Prof. Price says "No. 1 would produce after burning a first-class quality of lime," which is apparent to all, as shown in the high percentage of the analysis. Another desirable quality which it possesses, above any other lime used on this coast, is its power of retaining strength after being exposed to the air. "On the east and west sides of butte No. 1, the ledge has been opened sufficiently to give a tolerably fair view of the general structure and

Chemical Characteristics

Of the mass. In some portions of the bed, the rocks are drusy, and have become strongly impregnated with oxide of iron, alumina and silicious matter from water infiltration. This drusy rock burns into lime as readily as any other portion of the bed," and yields the finest quality of hydraulic lime, as shown by the following analysis made at the same time and by the same competent chemist as No. 1.

Certificate of Analysis—No. 2.

Limestone deposited by Mr. H. C. Blanchard. One piece of limestone.

Ingredients.	Per cent.	Carb. of Lime.
Lime	48.72	86.95
Magnesia	.86	.....
Alumina and Oxide of Iron	3.85	.....
Carbonic Acid	39.14	.....
Silica	7.22	.....
Water	.21	.....
	100.00	86.95

This sample was from rather an under average of the bed, much better could have easily been obtained, but as an "average" was desired it will serve to prove its quality, still a comparison between it and that made at Roudout, N. Y., (which is supposed to be the best made in the U. S.) will give a better idea. An analysis made by Prof. Beck, of the

Rondout Rock

Showed the following: Carbonic acid, 34.20; lime, 25.50; magnesia, 12.35; silica, 15.37; alumina, 9.13; peroxide of iron, 2.25. By reference to Prof. Price's analysis of No. 2, it will be readily observed that Blanchard's surface rock is superior in caustic strength, as well as other requisites of first class hydraulic lime. These samples, in connection with the many practical tests made by competent and impartial mechanics, conclusively proves in every respect its superiority over any other made or imported to the coast.

As before intimated, the possession of the valuable calcareous deposit has caused Mr. Blanchard to exert all his energy to further its full and proper development, in which he has not only added largely to the interest of Lyon county, but those of Ormsby, Washoe and Storey, especially the latter, where, owing to the large amount of building in progress, a great demand exists for lime, so much so, that we are informed by the agent, Mr. C. H. Clark, No. 164 South C street, Virginia, that he is constantly pushed to meet the demand. To supply this, the three large kilns have been kept burning at their full capacity, and it is the intention to erect another of greater dimensions on the Eastern side of butte No. 1.

On this Work

Quite a body of industrious workmen are constantly employed; in some cases double shifts being engaged, one by day and the other by night, who are under the foremanship of Mr. Charles Fleury, an able and experienced workman. A large and well-regulated boarding house has been erected by Mr. Blanchard, for their benefit and comfort; while in a small ravine, some 4,000 feet southeast from the quarries, there exists a perennial spring of fresh cool water, from which pipes have been laid conveying it to different parts of the premises where most desired. A large number of teams are constantly employed in transporting the lime to Dayton, over well constructed roads, from which point it is forwarded to the localities desired; while others haul wood from the adjoining hills to be used in the kilns. In fact, "Blanchard's lime quarries" daily presents an animated appearance, and the bright light from the burning kilns of a night show that an enterprising spirit of industry has found a home among the barren knolls and buttes of El Dorado canyon. As it is beyond calculation to estimate the amount of lime contained in the two quarries, one can only conclude with the pleasant thought that at least one of the many minerals of Nevada has given to one of her pioneers a never-failing income for life.

R.

Virginia City, July 17th, 1876.

THE Secretary of War has sent to the house a dispatch from General Sheridan recommending the increase of the second, third, fourth, fifth and seventh cavalry companies to 100 men, as was done for two regiments on the Rio Grande, and submits an estimate for the men required. In addition to the 2,500 men authorized by law, the number required to fill a regiment of cavalry on the frontier and in Texas, to the maximum of 100 men to each company will be 2,500; total expenses, $1,634,700. General Sherman prefers regular enlistments to volunteers.

CORRESPONDENCE.

Alpine County—Its Mines and Resources, Past, Present and Future.

[Written for the PRESS by VICTOR HARLAND.—No. 3.]

Silver Mountain District.

Within thie district, which is the oldeet and one of the moet prominent in ths conntv, are located several of the most promieing locations therein, and of which your correspondent will endeavor to present a fair and unexaggsratsd mention. Many of your readere will douhtleee rsmember the rush to this particular locality in "'63," and the almost unprecedented activity reigning there for some tims after its occnpation. Had the discovery been mads within the paet two or thres years, instead of at that earlier period, the trials and difficulties expsrienced here since that time would have proved but insignificant in comparison with those that have vexed ths mining public for yeurs. Our mining men were not then prepared for a war of economical reduction with rsfractory orse; though had more caution been dieplaysd in ths eelection of euitable furnacee, a great majority of the failures which have occurred would havs been prsventsd, and this district, togethsr with othere within the county, would present an incalculably hetter and more prosperons condition than at the present time. This ie, howevsr, in no manner ths fault of the district, as with the many meritorious locatione eituated therein, together with its natural advantages ae a timber region, also its splendid water privilegee, it ie destined to again attract that attention from our mining men which will insure the permanency for its mines and business interests that it eo justly deserves. Most prominent among the many locations within this district, ie the property owned by the

Exchequer Company,

Situated about one mile distant from the town of Silver Mountain, and near the head of the Scandinavian canyon. This property, which embraces two or three of the original locations in the immediate vicinity of the present works, is owned by a Londcn ccmpany, and is worked steadily and upon an extensive scale. In the earlier period of mining here, the original locatore and ownere of this mine expended considerahle time end money in driving a surface tunnel, intersecting the lode at a point about 130 feet helow the surface. Here, even at this nominal depth, the vein proved very encouraging, and further explorations showed a pay chute of fine ore, of which assaye gave rcsults from $90 to $497 per ton. The lode upon which the present company are now making extensive explorations is a well defined vein from four to eix feet in width, easily traceahle upon the surface for two miles or more. Under the present management a two-compartment ehaft hae been eunk to a depth of 400 feet, with drifts of varioue lengths along the lode upon the higher levels. The lode was penetrated by the shaft at the 200-foot level, the rugged nature of the grond undoubtedly being the cause that prevented a greater depth being attained hefore cutting the vein. The Exchequer—formerly termed the Buckeye—has, ever since its discovery in the earlier days of the district, been the object of attention throughout the county, and the progre-e and discoveries made therein from time to time have been anxiously awaited hy all interested in its prosperity, and especially those who have similar locations and mining intereets in the immediate vicinity, for in a great measure upon the succese or failure of this company depends the ultimate prosperity or adversity of the district. The diecoveriee in the different levels have been of euch character as to give the public a firm belief that with suitable machinery at the mill for reduction purposee, and the erection of a furnace that will thoroughly deculphurize tho ores, the day is not far distant when the Exchequer will become—in compariaon with othere of like dimeneions—one of the hest producing minee on the coast.

The Ore

Is of that clase known ae ruby silver, and the regularity of the lode, hoth vertical and upon the surface, proves it a true fissure vein of great etrength in both charoter and outline. In many places along the vein, taken from the different levels, beautiful specimens of ruby ore have heeo extraoted, and yielding an assay value of $3,000 per ton. These of course are exceptional, but the ore being taken from the pay chute mentioned and othera of like nature along the vein, indicate a proximity of larger hodies of great value at no great distance helow the present workings. The depth recently reached hy this ccmpany is 400 feet, from which level a drift will be run to cut the lode. Should the appearance ot the lode, and the quality of the ore at this level he in comparison with that fouud in the higher levels, it is safe to predict that thie mine will soon he in a condition to realize all that has been expected of it. In addition to the property above described, the company own a good substantial steam mill, with saw mill attached, which latter is run hy water power. The mill at preeent contains a hattery of eight stamps with pans, eettlers, etc., sufficient for mors crushing power, but, with the introduction of 10 additional stamps and ths ersotion of an O'Harra furnaos of 30 tons capacity, ths mill will soon he in a condition to rsduos ths ore that ie daily heing extracted from the mine. An almost inexhauetible supply of the finest timber, in closs proximity to hoth mins and mill, completss ths list of the valuahls possessions of this company. Ths machinery in uss and ehortly to be introduced in hoth mine and mill ie of a psrmanent and substantial nature, and

The Furnace,

Which will be ersoted as soon as possible, wae decided upon after a carefol examination of its merite (while in activs opsration in Peavine district, Nev.) hy ths manager, Mr. Chalmers, who visited the dietrict for that purposs. Mins owners and managere in this county have been so repeatedly duped by worthless monstrositiss, misnamed "chloridizing and desulphurizing furnacee," that it is a mattsr of no surpriss that at this late day thsrs should be but one patent contrivance of that naturs within the county, which is eusceptible of performing one-half the dutiss advertised as a guerantee by partiee interested in the conetruction, hut after having rscsived the careful attention of Mr. Chalmsre, who is psrfsctly competent to judge of its working capacity and msrits, it is to be hoped the O'Harra furnaos may bs all that is olaimed for it by the inventor, and by a succeesful treatmsnt of the ores to be introduced from ths Exchequer, put to hlush the fraudulent constructione which, although having the same aim in visw, are nevertheless utterly worthlese in their operation.

Owing to sxtsnded improvemsnts upon ths mins and mill, the working force of this company has heen necessarily lnrgs aod sxpsnsive, but having now already erected and in progrese ths machinery and improvements neceesary for a perfsct and permanent devslopment of their property, there ie no reason why a sufficient amount of milling ore of good qnality should not be produced to place this mine upon a firm hasis, self-eupporting, and to spare. Men of well-known mining abilities have visited this mine upon several occasions, and have, withont hesitation, prononnced their favorable and complimentary verdict upon the permanency and value of the mine. Experimental rune have heen made at the mill upon ore taken from the levele in the preeent ehaft, with eatiefactory reeults, and in these cases the old reverberatory furnece being ueed. With the succees which it ie hoped will attend the manager in his firet and all subsequent triale of the ores hy the O'Harra nrocees, and with a prudent and careful management of mines and mills, the fnture awaiting the Exchequer company is as bright ae the noon-day sun.

Centennial Chat.

[Written for the PRESS by MARY MOUNTAIN.]

I have been trying to imagine a pen driven hy the concentrated brain power of the whole quizzing multitude, who gather and scatter here day after day, and wondering if such a pen could poseihly present enough of the reality to satisfy the distant reader. For my own part I dare not think of the distant reader; but I drop like a coward into the pleasantest corner I have found yet; where the invitation ie always standing, "Come in and read your own home paper." This ie Rowell's newspaper pavilion, where more than 8,000 American publications of all eorte are constantly served up fresh and filed away in the moet orderly manner.

Surely nothiog could have been invented more homelike than this quiet retreat, close by the lake and the cool chief fountain, where you can take an easy chair and rest at a great rate while eximming the very top cream of the last PRESS. That means a dip into Mr. Ewer's lettere, and a dangerous dip it is for me—just takes all my courage away to note with what a vigoroue air he grapplee thie immensity aa though it really can be handled, and, if it can, he is certainly the man to do it; so I may as well get myself into marohing order and hriug up the rear with various odde and ends. Before leaving Rowell'e for other centers of attraction I would like to expreee my thanks and admiration of the enterprise and editorial courtesy which hae spread out, free for all, this rare pleasure.

And now, if one is in douht whioh way to turn, the U. S. government building, close at hand, is so large and so full of interest that days and weeks might he epent there with great satisfaction. Last winter in rainy eveninge we were reading a series of articlea upon

The Stone Age,

With illnstratione of the moet remarkahle relics found. So when we came upon whole cahinets and long rowe of glaee oases filled with venerahle fossils, genuine war-clubs, tools, images and all eorte of antediluvian tale-bearers, we were delighted to be on epeaking terme with them and, looking as wise as poseible, we marched from case to case, tracing the progress of

Pre-historic Man.

I think it was ahout the tenth case where he began to eat hash, and here was the original flint chopping knife, broad and remarkably well preserved. His progress was very rapid after this, and he or his wife hegan to indulge in heads, charms and other little flinty fripperies. Just as I had discovered a cunning little flap-jack ehovel, and was trying to make out whsthsr it once had a long handle like mins at home, up came a briek and portly eight-eeer, who openad hoth eyes and month with astonishment at each a lcng array of arrow-heade, slinge, daggere, battle-axee and othsr more peacahle toole.

But his gentle companion had sharp elbows, and used them nudgingly as shs cried out, "Oh, do hurry up! Who caree for a mees of old rocks!"

Thie wae pretty ssvers anubbing for the mound builders, and I fear this dumb story of ths peculiar hardware and hardship of their livee will ever seem to that astonished man liks the broksn fragments of a dream. I call it a dumh story, writtsn here in stons and clear, hard flint; hut will our own records of lifs and labor he more enduring?

The columns snpporting the roof over this collsction of relics ars decoratsd with the hugs, grinning idole and monetrous imagee mads hy those tribee who found it necessary to give form and color to their religious notione; but very liksly we do wrong in accusing them of actually worehiping theee pot-hsllied deformities. We might, perhape, as justly accuss the modern Chrisiian of worshiping hie luxurious church and big organ.

Nearly svery creed builde symhole hstwsen itself and God; and it is quite poesihle that ths pagan who carvss an image may he as truly devout as he who carvse a pulpit.

These old imagss have absurdly hig nosee, and perhape thie provss how venerable and well-founded is the belief that power and breadth of character may alwaye be found behind a hig noss.

Not far from here may be found

Models of the Cave Towns

That still exist in good stats of prsservation along the Colorado canyons. They ars cut in the sides of high hluffs overhanging ths river, and the town repreeented hy the model has a central house of three stories, with wings of two stories extending each way, and all the houses are connected with each other along the whole line of 600 feet.

Theee ancient cliff dwellers evidently understood the advantage of co-operation, and from samples of their handiwork epread ont helow the models of their houses, we see they knew how to furnish their homee with dishes and haskets, matting, corn-grinders, woven cloth, tanned skine, and varioue tools for agriculture and manufactures.

They also had leisure for gamee, and we see here a hundle of worn old sticke they used for countere in eome dead and gone style of gamhling. Some of their pottery was hrightly painted, and eo well glazed that the colors are still fresh.

Passing from theee relice of a people who were proud, happy and industrioue long before America was dreamed of by Columhns, we come upon a section of an oak tree whioh etood inside the en renchmente near Spotteylvania court house, and wae cut down hy musket balls in an attempt to recapture the worke. Several bright-eyed hoys hang around the rough old stump and slyly ran their fingers along the hullet gashes; but fingering ie not allowed becauee of the remorseleee relic huntere who would make short work of a dozen euch stumps if they had the least chance.

Here are four of the queerest old aix-pounders, looking so very historical one is sure to hunt up the card which telle ue they belonged to Revolutionary fathere, and were

Presented by Lafayette.

Close by is an ancient breech-loading cannon dating hack to 1570; a relic of the early Spanish occupation of Mexico, and with etill brase enough to look squarely in the mouth of a fine modern gun, one of a hattery of Whitworth guns, presented hy loyal Americans in Europe to the U. S. Government in 1861.

All around this point are warlike sights and sounds enough to stir the pulee of a voteran or put an extra strut into the proud walk of the "West Point cadets," who survey the world's fair with the cool, critical glance of those who know all ahout it. And what are the warlike eounds? The clang of machinery making cartridgee and turning out gune—more and more improved guns.

Winding its aweet way among the big noisee comes the eound of martial musio, and there goee a hand playing "soldier tunes." A crowd always followe the band, or rather any hand that marchee, and we have here eeveral of the finest bands in the country. A marching band is alwaye supposed to lead on to glory of eome sort, and ever since the cadete encamped out there heyond the great eawmill,

Their Dress Parade

Is alwaye eurrounded by admiring crowds, and more young ladiee than you would care to count.

It was rumored one afternoon that these straight young soldiere were to show ue their last parade and then hreak camp for the return trip. Ah, the girle looked sorry, and some were sisters, to be sure, and pointed out "Will" or "Tom" in tones that enlieted all my sympathy.

"See, there'a Will eweeping out the third tent in the fifth line. He knowe I'm here, but he don't *hurry*. How long he ie putting things tidy."

"Well he might he," growls the envious young hrother; "if he leaves even the washdish slack wont he catch it? All the cads are down on somehody 'cause he wouldn't let 'em hring hut 10 pairs o' white pants for 10 daye. O, my! And then there'e the gray pants anyhow, and how many more d'ye think they want? I tell ye Bell, they feel awful etuck up," etc.

By and hy Will hae ths tent in order for inepection and comee ont to see Bell. I could easily admire hie soldierly hearing and lofty stride; but hie stiffnsse tnward poor Bell nearly eet my teeth on sdgs, for he looked ae if eisters were nothing but a bother; and as he marched off with Bell and the youngsr hrothsr, the hystandere growled a little ahout Weet Pointers being a "epoiled est of fellowe." The care come up again and again loaded with ths hundrede who liks to help spoil the cadete, and they all wait patiently in ths broiling eunehine while the officers inepect arme and mueter ths companies for their usual drill. It ie all new to ms and really quite beautiful to eee the harmony of motion all along ths line and all ths boys looking so full of spirit and etrength. Aftsr ths drill tents were not struck and word went arnnnd that further leavs of abeence wae hoped for and "mors whits pants." They were highly favored in being allowed to camp on the Centennial grounds, whers thie little village of whits tents contrasts finely with ths handeome architecturs of eome of ths largeet buildinge in the world.

Returning from parade we again paes along the shady eide of ths great eawmill and notice the enterprise of Canada hsrs as well ae in all other departmente. In the main building, in agricultural hall, in machinery hall and in the art galleriee, Canada hae distinguished hereelf and many of her provinces have eent spscial exhibite of grain, furs and minerals, pottery and beautiful iron work. Then ont in the grounds they havs a quaint log houss to represent the hackwoode, and eoms sections of their hig trees, lumber, etc.

I was delighted ons day to come upon a rathsr quiet nook in the main building filled with cnriosities "from Greenland's icy mountaine." All eorts of furs made up into cloaks, shirts, boots, mittens and stiff little petticoate and hoods. Then there are odd looking tools, models of the native hoats, with all sorts of fishing, hunting and domestic implements, not gilt-edged for the occasion but such ae they are actually using. The hunches of sinew for thread, the clumsy needlee and pine made of fish hones and many other things represent to us the hardship of their narrow lives. Yet they have some idea of "trimmings," and much of the native work was ornamental as well as useful. Some chubby Arctic ducke stood peering with glass eyes into a great nest of beautiful sea fowl eggs. All this was included in the department of Denmark, and that must have separate notice.

The Working Facilities at the Eureka Consolidated Mine.

Last Monday, for the first time in several months, we visited the Eureka Consolidated works, on Ruby hill, and were greatly surprised to notice the many improvements which have been made there since our last visit. Everything is in excellent working order and the machinery for working the mine as perfect and complete as wae ever erected in the state, not excepting the most expensive worke on the Comstock. The engine and machinery are capahle of hoisting from the ninth level, a depth of 730 feet, 1,000 tons in 24 hours, and are of sufficient power to do all the hoisting that will be required until a depth of 2,500 feet ie attained, and will perform all the work, including the raising of the water in tanks, for a depth of at least 500 feet below the ninth level. About 50,000 gallons are now being taken out in 24 hours and it ie not probable that the volume will increase until the level of the valley is reached, which ie at least 500 feet lower than the depth attained. The tank in which the water is raised holds 500 gallons; it makes the round trip in three minutes; consequently, it will he seen that the machinery is only employed five hours of the 24 in keeping the mine clear of water, leaving an abundance of time for the employment of the machinery in hoisting ore, weete, etc., and the performance of such other work as may he necessary. Near the engine is an air compressor of sufficient capacity to furnish underground at the ninth level the amount of 30 horse power. By thie the Burleigh drill is worked, the compressed air being forced down the shaft in pipes and carried into the drifts where the instrument ie used in strong gutta percha hose. A small engine has also been erected at the ninth station, to be used below that level. This engine will he run hy air, from the compressor on top, which will furnish sufficient power for a couple more of the seme capacity. The water thus pumped will be discharged into the sump at the ninth level, from whence it will be taken to the surface in the tank. Another great labor-saving improvement, is a railroad incline now in course of construction from the bottom of the ore dump to the level of the hoisting works. The grade ie 18 degrees, and the cars will be drawn up hy a stationary engine at the top. Thie will save the rehandling of mining timhers, wood, coal, and other supplies for the mine, which at present are unloaded at the dump, from whence they are hauled to the shaft by teams. When this is completed, everything about the mine will be as convenient for working as can he rendered hy human ingenuity. The indications at the ninth level are all favorable for the speedy discovery of an ore body, which is all that ie wanting to place the Consolidated upon the list of the dividend paying mines of Eastern Nevada.—*Eureka Sentinel.*

MECHANICAL PROGRESS.

English Minting Operations.

From a report of Mr. Bramwell, engineer, may be gathered an insight into the nature of the processes connected with the manufacture of English coin. "The metal, in ingots, as it is received at the mint, is melted in closed crucibles heated by a perfectly smokeless (coke) fire. The required alloy is made in the process of melting, and the mixture is poured into molds. The bars resulting from the castings are then rolled down into fillets of suitable thickness and width for the intended coins. From these fillets the blanks are cut, and these blanks, after having been marked (i. e., thickened at their edges), are of suitable dimensions for the finishing operation, that of impressing on the blank the device appropriated to the particular coin. During the preparatory processes the metal has to be annealed two or three times; this is done in close vessels, which are heated in smokeless furnaces. After the pieces are coined they are passed into the weighing room, where each is tested in automatic weighing machines. Ancillary to the above described operations are the preparation and repair of the various dies, involving the use of two or three turning lathes and of fires for hardening and tempering. Formerly the presses used for cutting out the blanks and those employed in coining acted by percussion; they were screw presses, fitted at the tops of the screw with heavy swinging weights, which on being put into motion caused the screws to descend, and caused the upper die to strike the coin, which acted as the stop to arrest the momentum of the press. Such presses were undoubtedly noisy, although not nearly so noisy as an ordinary steam printing press, but such presses are now discarded as regards the cutting out the blanks, and for coining a simple press of improved construction is in use. This improved construction is one wherein the coining is done silently by pressure, instead of noisily by percussion. The rolling and drawing machinery is quite quiet, as are the engines which work it. The furnaces for the engines are absolutely smokeless, being on the 'Jukes' construction."

AMERICAN STEEL.—Within the last few years, says the New York *Sun*, the standard of American steel has been greatly elevated; so much so that in all staple lines, such as cutlery, pitchfork, gun, file, hoe, rake, axe, and agricultural steel, foreign goods have no standing. But one cutlery concern in America is using foreign steel, the great bulk of all the table cutlery being now made from American ores, converted into steel and rolled into shape in American mills. This is also true of wire rods for drawing into merchantable sizes and shapes. American hay forks have no superior for durability and adaptation to their purpose, and it was recently noted in an English trade journal that the growing trade in English markets of American makers of hay forks had seriously interfered with their own orders. Steel is lower in price in America now than it has ever been before, yet better in quality, and notwithstanding the unsettled condition of trade, is still made in large quantities. It is one of the most active and important of our industries, demanding millions of capital and employing some thousands of skilled workmen and laborers. The city of Pittsburg, Pennsylvania, is the seat of the largest steel works in the country, but there are several in Jersey City, Philadelphia, Newark, and at other points. A visit to one of them would amply repay those curious in such matters.

THE RAILWAY OPERATIONS OF 1875.—The operations of the railway companies of the United States during 1875, as summarized in the advance sheets of Poor's Manual, are by no means destitute of encouraging features. The reported amount of dividends is greater than in the preceding year, being $74,294,208, as against $67,042,942 in 1874. The most important increase is in the dividends of the Pacific railroads, but there is also an increase in the aggregate dividends paid on the lines of the New England, Middle, Western, and Southern States. The total diminution in the gross earnings amounts to $17,400,511, while the net earnings only show a decrease of $4,064,520, —a result that bears emphatic testimony to the remarkable efforts of the railway companies to economize expenditures and reduce the cost of transportation. The reduction in gross earnings was especially heavy in the Middle States, and their railways accomplished the task of suffering a loss in gross earnings of $10,821,020, while the net earnings were only reduced $4,579,554. The reported results on the Western lines are still more extraordinary, as their gross earnings declined $8,651,823, while the net earnings were diminished only $57,409.—*Railway Age.*

INTRODUCING THE BLAST.—The Hsmoir process of introducing a blast into molten pig iron between the time that it leaves the blast furnace and being poured into the ingot-molds has been the subject of prolonged experiment by French and Belgian metallurgists. It is now found at the Maubeuge iron works that a saving of 10 per cent. on the coal for the puddling furnace is effected by the partial decarbonization due to the blast; with the same quantity of coal two charges more are obtained per furnace per 24 hours.

Steel Wire Hawsers vs. Hemp Hawsers.

An important trial took place last week, by order of the Lords of the Admiralty, at Devonport dockyard, conducted by Captain Youel, the Master Attendant, and witnessed by Admiral G. O. Willes, C.B., and other officers of the yard. It is the custom at the government dockyards to keep in store 25-inch end other large sizes of hemp hawsers for use in cases of emergency, as in the instance of Her Majesty's ship *Agincourt* getting on shore, when these hawsers were sent out to assist in getting her off. In the finest weather, and under the most favorable circumstances, it is with the greatest difficulty these hawsers can be handled. Mr. Bullivant therefore obtained permission of the Lords of the Admiralty to test his 8-inch patent flexible steel wire hawser of equal strength, against the 25-inch hemp hawser as used in the service. The 120 fathoms of 8-inch steel wire hawser tested weighed 50 cwt., and was coiled on a reel, the outside measurement of which was five feet square. The 25-inch hemp hawser was coiled in a tier 42 feet long and 14 feet wide, and the weight to 120 fathoms is 150 cwt. Each hawser had an eye spliced in the end ready for use. Twelve men were told off to work the 8-inch steel hawser, which they hauled off, ranged along the ground, with the greatest ease, and two men took two turns around a gunpost one foot in diameter, without any injury to the steel wire hawser. Forty-eight men were then told off to work the 25-inch hemp hawser, the eye and thimble of which were so large and heavy that it was found necessary to provide two large trucks in which to move them; trussels were also laid along, on which the hawser was hauled to a post 18 inches in diameter, round which one turn was taken with difficulty. A wish was expressed by Mr. Bullivant that the hawsers should be put in and laid out from a boat, as it would be necessary to do in case of requiring them to get a ship off the shore. This was, however, considered quite unnecessary, as it had been so clearly shown that 12 men could work the flexible steel wire hawser far easier than 48 men, assisted with trucks and trussels, could work the 25-inch hemp hawser; and it was also stated that no ship in the service carries a boat in which the 25 inch hemp hawser could be coiled and paid out.—*Iron.*

THE ENGLISH PATENT OFFICE.—Several changes are impending in the arrangement of this office. An order has just appeared which puts an end to the abridgements of provisional specifications, which have, since 1866, been required from each applicant with his provisional specification. This will be a slight relief to inventors, and it is only an official acknowledgement of a fact that has long been obvious to all concerned, that these so-called abridgements were quite useless for any purpose whatever. This order is to take effect on July 1st. Notice is also given that, in future, the drawings accompanying specifications will be reproduced by photo-lithography, and the copies of the original filed for reproduction are, after June 30th, to be sent in in a condition such that they may be copied by means of photography. It is understood that it is intended to make a considerable reduction in the scale on which the drawings are published, with the object of economizing space and lessening the cost of printing. In order to give time for the examination of the filed drawings, the Commissioners of Patents request that they may be sent in at least six days before the expiration of the time allowed, thus limiting by a week the six months' provisional protection granted under the Act of 1852.—*Ironmonger.*

A NEW SYSTEM OF PLASTERING.—Builders, owners and tenants of city houses will doubtless view with interest a new system of plastering, which is claimed to prevent the sudden and disastrous downfall of ceilings, so frequently occasioned by defects in the water pipes and consequent leakage and overflow. The invention consists of replacing the scratch coat and brown coat used in ordinary work by the combination of fibro-ligneous sheets with a cement composed of lime, sand and plaster. The sheets are of a fabric resembling coarse bagging, which is secured to the lathing, and the cement is supplied in the ordinary way. A hard finish coating completes the work.

PROGRESS IN JAPAN.—We are informed that energetic measures are being adopted by the government for introducing the improved manufacture of iron into the country. With this view, two charcoal blast furnaces and other works are in course of erection, and it is expected that by the close of the present year 12 puddling and seven reheating furnaces, to forge train plate, rail and bar guide mills, with steam hammers, four different shears, saws, lathes, cranes and all other necessary appliances of the most modern construction, will be in operation.

CARBON BRONZE—Messrs. B. W. Baldwin & Co., Pittsburg, Pa., have been very successful in introducing carbon bronze for use in hot work and heavy plate rolls. It has been found very durable, and it is the opinion of many persons thus using it that carbon bronze journal bearings will wear at least twice as long as those of any other material. During a use of four and a half years, not one instance has been reported of heating or cutting journals. The metal admits of a wide range of uses, and possesses a substantial value for the purposes for which it is recommended.

SCIENTIFIC PROGRESS.

Efforts to Use Solar Heat.

The last number of the *Revue des Deux Mondes* contains an article on the labors of sundry scientific men intent upon putting to use the heat of the sun. The *Pall Mall Gazette* summarizes the article. In France, it says, M. Mouchet, Professor of Mathematics in the Lycee of Alencon, has been engaged since 1869 in experiments. His first were made with a vertical copper boiler, blackened externally, so as to absorb the incident rays, protected by three concentric bell glasses, and resting on a badly conducting surface, such as sand, brick or wood. Throwing on this boiler the rays from a metallic reflector, M. Mouchet found that he could dispense with two of the bell glasses. He succeeded in vaporizing water and infusing sulphur, which requires a temperature of 110 deg. Centigrade, and at the end of 20 minutes of exposure he raised the temperature of his boiler when empty to 200 deg. Centigrade. He subsequently fused tin in two minutes, lead in five, and zinc in six. The quantity of metal in each case was a kilogramme, and the degrees of heat required were 235 deg., 335 deg. and 475 deg., Centigrade. The first practical use made by M. Mouchet of the rediscovery, or rather reapplication, of a force that Archimedes had rendered available as a military engine of offense during the siege of Syracuse, was in the humble but important department of cookery. His exhaustive solaire was a glass jar, in which was placed a cylinder of copper or wrought iron, blackened without, and resting on the bottom of the jar. The whole was closed by a glass lid. A cylindrical reflector, plated with silver, cast the concentrated rays of the sun on this apparatus, in which an excellent soup was made in four hours, perfectly cooked, an unusually fine flavor being attributed to the regularity of the heat. This solar soup kettle has been simplified into a plain glass vessel, placed in the focus of a conical mirror of plated brass, in which vessel all kinds of viands—meat, vegetables or fruits—are cooked by the direct action of the sun. Tea, coffee, or any other infusion may be thus readily prepared in a Lyons beer bottle; or the vessel in the focus may be used merely for the production of steam, which is led off to a second vessel by a pipe, and thus boils any requisite quantity of vegetables in a short time. By substituting a box of wrought iron for the glass jar, a solar oven is formed, in which a kilogramme of bread, said to compare favorably with that baked in the ordinary manner, is baked in less than three hours. Roasting does not require so fierce a heat as either of the former processes. It is sufficient to suspend the meat to be roasted in the focus of the reflector without interposing any other vessel, either of glass or of metal. In less than an hour a joint, a fowl, or piece of game is well roasted. It is necessary to avoid the use of butter for basting, as the chemical rays of the sun convert this substance into butyric acid, which gives an abominable taste to the roast; but by interposing a yellow or red glass the chemical rays are arrested. Replacing the covering of the "marmite solaire" by a sort of alembic a distilling apparatus is formed. A tube led through a helix in the ordinary way is added, and in 40 minutes the distillation of two liters of wine may be effected. In this case also the flavor of the alcohol is said to be unusually fine in consequence of the slow regularity of the heat.

In 1866 M. Mouchet took the sun from the kitchen to the workshop, and at the cost of the Emperor Napoleon completed his first mechanical solar engine. An apparatus of this nature is now to be seen in the court yard of the library at Tours. A conical silvered reflector, 26 metres diameter at the base, one meter at the apex, and eight centimeters high, exposes four square meters of reflecting surface. The angle of the inclination of the sides of the cone to the axis is 45 degrees. The boiler placed in the focus of this hollow cone is double, being in fact a mere shell. The outer coat has a longitudinal diameter of 80 centimeters, and a transvereed diameter of 28 centimeters, while the correspouding dimensions of the inner coat are 50 and 22 centimetres. Thus a shell of water of three centimeters in diameter is subjected to the reflected heat, the contents of the boiler being 20 liters of water with a steam box containing ten liters of cubical space. The vacant space within the inner coat affords room for the steam and water pipes and for the safety valve. A bell glass of five millimeters thick (or 3–16 of an inch) is constructed so as to surround the boiler concentrically at a distance of five centimetres (or two inches). The object of this transparent envelope is to allow the free passage of the visible rays of light and heat that come from the surface of the reflector, and to arrest the invisible thermic rays that radiate from the blackened surface of the boiler. The latter is thus constantly surrounded with a cushion of heated air, excepting at the foot, where it is joined to the reflector. A clockwork apparatus is attached, by means of which the axis of the apparatus is kept continually directed toward the sun. The apparatus in question was erected three and a half years ago, by aid of a subvention from the Council General of the Department of the Indre and Loire. The result merits attention. On the 8th of May, 1875, the day being fine, 20 liters of water at a temperature of 20 degrees, Centigrade, were placed in the boiler at 8:30 A. M. In 40 minutes steam was generated with a pressure of two atmospheres, which gives the calculated temperature of 21 degrees Centigrade above boiling point. The pressure rapidly rose to five atmospheres, which was that at which the safety valve was weighted, as at this heat the sides of the boiler have to support a total pressure of 40,000 kilogrammes. Toward the middle of the same day 15 liters of water at the boiling point were raised in less than 15 minutes to a pressure of five atmospheres, equivalent to a temperature of 158 degrees Centigrade. On the 22d of July, about 1 P. M., the apparatus converted into steam five liters of water per hour, which is equal to 140 liters of steam per minute, or to about one-half of a horse power.

It will be evident to the reader that the one weak point in this scheme is the fact of the dependence of the solar marmite on the condition of the sky. That on a fine summer day any imaginable quantity of heat may be derived from the sun and utilized by the mechanic is not to be denied. But by night, during the winter, or on a rainy day, the motor must be powerless.

Does a Bird Die a Natural Death?

It is the opinion of some naturalists that birds never die what is called a natural death, but come to their end by some murderous or accidental means; yet I have found sparrows and vireos in the fields and woods dead or dying, that bore no marks of violence; and I remember that once in my childhood a red-bird fell down in the yard exhausted and was brought in by the girl; its bright scarlet image is indelibly stamped upon my recollection. It is not known that birds have any distempers like the domestic fowls, but I saw a social sparrow one day quite disabled by some curious malady, that suggested a disease that sometimes attacks poultry; one eye was nearly put out by a scrofulous-looking sore, and on the last joint of one wing there was a large tumorous or fungous growth that crippled the bird completely. On another occasion I picked up one that appeared well but could not keep its center of gravity when in flight, and so fell to the ground.

One reason why dead birds and animals are so rarely found is, that on the approach of death their instinct prompts them to creep away in some hole or under some cover, where they would be least liable to fall a prey to their natural enemies. It is doubtful if any of the game birds, like the pigeon and grouse, ever die of old age, or the semi-game birds, like the bobolink, or the "century-living" crow; but in what other form can death overtake the humming bird, or even the swift and the barn-swallow? Such are true birds of the air; they may be occasionally lost at sea during their migrations, but, so far as I know, they are not preyed upon by any other species.—*John Burroughs in Scribner's.*

CONCERNING THE VISIBILITY OF FLAMES.— M. Allard has published several memoirs on the transparence of flames and of the atmosphere, and on the visibility of flash light beacons and his experiments therewith. The flames most generally employed in lighthouses are those derived from oil lamps having many burners, with concentric wicks. M. Allard finds that the luminous intensities of these flames augment a little more rapidly than does the consumption of oil, and on comparing said intensities with the dimensions of the flames, that the former augment equally with the apparent surface, while they diminish per cubic centimeter (.06 cubic inch) in proportion as the total volume of the flame becomes greater. These results can only be explained by a defect of transparency of the flames. Different experiments lead to the adoption of the number 0.80 as the average value of the coefficient of transparency of the flames, referred to the thickness of one centimeter of flame traversed by the luminous rays. From several observations, the author has also determined that there is a state of transparency at which a light ceases to be seen from a given point. In the case of flash-lights, it is demonstrated that in the persistence of the luminous impressions on the retina, the law of decrease of the sensation is represented by an exponential function. The retina then acts like phosphorescent bodies of short period, when they are previously excited by light, and which becomes rapidly extinguished in darkness, since the law of extinction is the same.

PRIZES FOR SCIENTIFIC WRITERS.—The German gasmakers' association offer $400 for the best treatise on the method of separation of carbonic acid from the lighting gas made from common coal. The method proposed must be set out at full length, with scientific explanation of its mode of action and description of apparatus for its use on an economical working scale. Essays are to be sent in unsigned, but containing a private mark, to Dr. Schilling, at Munich, before December 31st next.

THE AMERICAN CHEMICAL SOCIETY.—An organization of professional chemists has lately been formed, having the above name, under the presidency of Prof. John W. Draper. The new society already boasts of a membership of over 100, including the most prominent chemists of the country. As an agent for fostering and promoting the development of chemical science in America, the society has a wide field of utility.

The Lumber Mills, Factories, etc., of Truckee and Vicinity.

[By our own Correspondent.—No. 5.]

Truckee was in great part destroyed by fire only a few years ago, and this accounts for the rawness of its appearance. It is not very large. I never once thought of asking the number of inhabitants, being too much taken up with the life, activity and hustle around me to count the bees swarming about its different hives of industry.

As their season is short, say from five to eight months, they have learned "to make hay while the sun shines." On every hand was heard the noise of hammer and anvil. The whistle of the steam saw mill responded in harmony with that of the swiftly passing locomotive, conveying away its lumber to supply the distant mines of California and Nevada, to build the village on the hill-side, a home for the valley farmer, or the palatial mansion of the richer inhabitant of the city.

The Amount of Business

Done here within a very limited area, along the line of the railroad from Truckee to Boca, a station less than 10 miles distant, is almost astounding, saying nothing of the wood, numbered not by the cord but by the car load, of planing mills, shingle machines, or ice storing. There are not less than one dozen saw mills, with aggregate capacity for cutting daily 350,000 feet of lumber, and turning out annually, perhaps 60,000,000 feet or more.

Mr. E. Ellen,

An appreciative reader of the MINING AND SCIENTIFIC PRESS, seemed gratified when asked for some items for publication. He had recently lost a large planing mill valued at $18,000, but, with an energy that knows no bulking, will soon be able to resume at his new mill in process of erection, three miles from Truckee. The lumber will be floated by flume to the railroad, the usual mode of conveyance in this region. His old mill cut last year 3,000,000 feet. Capacity of new mill will be, according to his estimate, about 5,000,000 feet, which is both modest and moderate as compared with some figures received.

Messrs. Martin & Leach, of the

Banner Mill,

Land their lumber at Camp 16, near Boca.

The mill is situated in the midst of what is claimed to be the finest timbered country on this side the Summit, and about eight miles from Truckee, on the line of a projected railroad from this point to Sierra valley, a preliminary survey having already been made. Capacity claimed for mill per season, 8 000 000 feet; actual cut for present year will probably reach 6,000,000.

The mill of Messrs. Lonkey, Smith & Hall, five miles from their two yards at Prosser Creek station, is run by a Myer & Leffell turbine wheel, and was reported as cutting, when visited, about 80,000 feet per 24 hours.

Their retail yards are at Virginia City, where they readily sell all they can cut, besides a large amount procured at other mills.

The Truckee Lumber Company's

Two saw mills are giving out their 50,000 feet per day, and may exceed 10,000,000 feet the present season, if expectations of the proprietors are realized. Their factory, with average of 45 men, is annually turning out 6,000 pair of blinds, 25,000 doors, 40,000 pair of windows, of which 20,000 are glazed; 20,000 boxes, 400,000 fancy dressed picketts, 3,000,000 laths, and of shingles 6,000,000 at least, besides a vast amount of turned work. Their mouldings will approximate 12,000,000 feet. Mr. Ware, the superintendent, has invented a new fancy door moulding, wholly of cast iron, made very thin and light. The preference given to it over wood is, that it is said not to swell nor shrink as wood, and to be far cheaper.

A Useful Invention.

Richardson Bro's. have a mill and also a planer, six miles from Truckee, where I had the pleasure of observing the working of a patent, secured sometime since through the MINING AND SCIENTIFIC PRESS Agency, the invention of Mr. W. Richardson, which seemed so useful and ingenious as to astonish me that it had not been brought into general use.

It is an incline block for carting logs on the carriage, enabling the mill to cut at least 3,000 more feet per day than by use of ordinary block. The blocks are hung on a hinge at one end within slotted floor-beams, and are elevated by an eccentric shaft, worked by a worm-screw, the sawyer raising a lever attached by merely pulling a rope, and readily managing the machinery without leaving his position.

Time and space forbid a detailed mention of the Schafer, McFarland, Alder creek and other mills about Truckee, so I pass to the

Vicinity of Boca.

The daily cut of Messrs. Bragg, Folsom & Co's., mill as ascertained on the ground, is 40,000 feet. The average yearly cut of the saw mill belonging to the Boca mill and ice company, is about 6,000,000 feet. The Pacific shingle company, Thompson and Ferguson, proprietors, have two of Huntington's machines, and are averaging for run of 24 hours, 85,000 shingles, and will probably reach for season 15,000,000, having estimated for bolts to that amount. The machinery is run by water, and the bolts by a device of their own, or rather by a special application of a well-known principle, are elevated by means of blocks fastened at suitable distances on a chain, being in this way passed into the mill from the flume, saving considerable labor in handling.

Mr. Doane and others have just finished a very large brewery at Boca, at a cost of $150,000, and fitted it up with the latest improvements, turning daily the barley of the farmer into 75 barrels of beer, and giving employment to about 25 men.

One of the great products of this vicinity is

Ice.

Formerly almost the entire supply was from Sitka. Now, with the exception of what is produced by artificial means in San Francisco, all is furnished either by the Peoples' ice company at Truckee, which stored last winter about 4,000 tons, or by the three following companies, viz: The Summit, the Nevada, and the Boca, now consolidated into the Pacific ice company, with principal office in your city. The Boca company has a house 480 feet by 40. Capacity, 8,000 tons. The quota of the Nevada company is at present furnished by

The Summit Company,

Which has houses at the summit, and also at Prosser creek, at which place the most of the business is now done. The reasons assigned for transferring their business here are there is less snow to contend with, and that it is much colder, although 1,000 feet, at least, lower than at the summit, owing to the currents of air produced by the peculiar topography of the surrounding country, as connected with the valleys nearer or more remote, or adjacent mountain ranges. The capacity of the Summit company's house is 10,000 tons, and owing to the increasing demand, the intention is to erect another building as large as the former.

The Dam

On Prosser creek, covers 36 acres, giving employment to 150 or 200 men in the winter, scraping the snow from the ice, cutting it into blocks, usually about 22 inches square, and sliding it down an incline to the house, where it is stored for the summer market. The cutting is done by plows made expressly for the purpose, and drawn by horses, one occasionally sharing the fate of an icy grave.

I examined with some considerable interest here

A Fish Ladder,

Of somewhat peculiar construction, modeled, it is said, after the design of that at South Hadley falls. It was built under the superintendence of the State Fish Commissioner, the Hon. B. B. Redding, and is certainly worthy of imitation elsewhere. In consequence of the numerous offsets in the ladder, some 12 feet in width, and the endless zigzagging, requiring a mile of travel, perhaps, to make the distance of 100 yards, the ascent to the dam can be made as easily by the fish as in almost any other portion of the stream. K.

SIX companies of volunteers have gone from Halifax to the Sydney, C. B., coal mines. The manager of the mines was shot at on Thursday, and the striking miners tore up the railway track and emptied the coal wagons. The miners say they are determined to resist a reduction of wages, and will prevent the shipment of coal during the strike.

A NORTONVILLE dispatch reports two more deaths from the mine explosion on Monday week. The deceased were Thomas D. Davis and Thomas D. James.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

TO BE PATENTED.—Alpine *Chronicle*, July 29: Robert M. Folger, attorney in fact, has been instructed to apply for a United States patent for the Globe mine, located at Monitor.

BEING SURVEYED.—U. S. Deputy Surveyor Hawkins is this week surveying the Balaklava mine for the purpose of having it patented.

ACCIDENT.—On last Thursday week, at Monitor, Supervisor Mercer fell from a scaffold while at work at the hoisting works of the Advance mine. The shaking up he received necessitated a settlement by a retirement for about a week.

EXPECTED.—Parties from San Francisco are expected here next week to examine some of our mines.

CALAVERAS.

SHEEP RANCH MINES.—Calaveras *Citizen*, July 29: The mining news from this camp is encouraging. The tunnel of the Good Hunter is being pushed forward, and we believe that a contract to continue the Pioche tunnel 100 or 200 feet will soon be let. The Sheep Ranch mine still continues to pungle and is likely to do so for an indefinite period of time—so miners say.

FOUND IN A SHAFT.—We just lately learned that a young negro boy about 18 years of age was found drowned in a shaft, near Angels. The body was so decomposed that it was thought best to bury it by filling up the shaft. The boy, whose name was Bell, had been missing for several days when discovered.

MARIPOSA.

BARRETT MINE, HUNTER'S VALLEY.—Mariposa *Gazette*, July 29: This well known quartz mine, owned by Messrs. Barrett, Carson & Pillians, has, as we are informed, been sold to a company for the sum of $15,000. It is expected that this company will soon put on a large force of men. They are now prospecting and preparing the mine for a general upheaval of the glittering ore, of which this mine has produced in large quantities but a few years since.

NEVADA.

MOORE'S FLAT MINES.—Cor. Nevada *Transcript*, August 1: Our miners are busily at work on their claims, and the high gravel banks are rapidly disappearing under the pressure of heavy streams of water. The Boston company has just opened their upper tunnel and shaft, through which they are running the climb that had slid in last winter. They have a large monitor, running 1,600 inches of water, and this quantity will be increased as soon as the lower tunnel and shaft are opened. They have a full crew in the tunnel, working two shifts. Jim Beddington, the foreman, is decreasing the pile of pipe-clay in the Boston claims, but there is an enormous quantity of this to be washed off before the gold can be got. In the course of a few months this mine will be cleared, when the number of hands will be increased. The Blue Gravel company will be ready to start their machinery on the 1st of August. The pumping and hoisting will be done by water power. A water wheel turned by 25 inches of water, with a pressure of 216 feet, will do all the necessary work required. The people have great expectations of this mine, and think the company will get ample returns for their labor. Blue gravel has been found on the ridge above the shaft, with gold in it, and it is supposed this stratum extends along the flat on which the mine is situated. Hegarty & Co. have moved their barn, and in a few days more the store will be moved also. Much of the town will not be moved before fall. If the Blue Gravel company find a good prospect the town will be built close by the mine; if not, it will be built at Jerico. At present the store is the only building started at the new town.

CURRY & RANDALL'S quartz claim, on Rush creek, is looking splendidly. They have a very fine ledge, and are taking out a large quantity of rock, which will be crushed in a few weeks.

THE mining prospects about Wolsey's flat are looking better than they have for a long time. We understand Marks & Co. will soon give employment to several hundred men in drifting some ground they own there.

PROVIDENCE.—We saw a nice bar of silver on Saturday, which was part of the result of a working of a lot of sulphurets at the Providence mine. Heretofore the silver in the rock of that mine has not been saved by the process used. Verily there is a new era inaugurated in mining here. There are three new processes now in operation in the county, either one of which will save a large percentage over the old methods. We shall give a description and fuller particulars about them shortly.

SISKIYOU.

CLEANED UP.—Yreka *Union*, July 29: The mill of the old Mecklenburg company, which has been running for the past few weeks on rock from that claim, was cleaned up yesterday, but we have not learned the result. It is not expected to be very large, however, as it is generally supposed that Eisenbeck, who was one of the proprietors and amalgamator until recently, and absconded last week, has taken a good deal of amalgam with him. The quartz of this ledge looks well, and prospects well, though in the mill under Eisenbeck's manipulations it has not paid well. The men in the mine who got out the rock express the greatest faith in its quality, and think that with an honest mill-man the mine will pay well.

PAID WELL.—Trinity *Journal* July 29: We were this week shown a small bucketful of gold dust—45 pounds of the precious metal—taken from the Ward mine, on Oregon Gulch mountain, and being the result of the final clean-up in that claim. This is about one-half the yield for the season, $17,000 having been taken out altogether. When the limited amount of gravel washed is considered, the yield is regarded as a splendid showing for the mine. Early in the season there was a great deal of trouble with the ditch, it being new and causing much delay and expense through slides and caves. An extensive deposit of clay and slide bedrock, containing no gold, had to be removed before the gravel was reached, and it was therefore rather late in the season before any pay dirt was washed. The result was such, however, as to give satisfaction to parties interested, and prove that the gravel is very rich. Mr. O. M. Loveridge, the superintendent, now has everything about the claim in tip-top shape, so that but little expense will be required to place it in working order for another season.

Nevada.

ANTELOPE DISTRICT.

ENCOURAGING.—Eureka *Sentinel*, July 25: Antelope district is situated in the Sulphur range of mountains, about six miles east of Garden Pass, on the Eureka and Palisade railroad. It is most eligibly located for economical mining, and is well supplied with both wood and water. There are about 30 miners in the district, all busily engaged in developing their claims. The principal mines are the Manhattan and Justice, both of which are showing remarkably well. These claims are supposed to be on the same ledge, which is easily traced for a long distance. Shafts have been sunk to a depth of 70 feet, disclosing three feet of ore that goes $75 to the ton. The formation of the country rock is especially favorable for the existence of permanent veins. We are glad to hear these encouraging reports from Antelope, and hope the mines of that locality may turn out to be as rich as the hardy owners could wish them.

CORNUCOPIA DISTRICT.

LIVELY.—*Silver State*, July 24: Asa Moore arrived from Cornucopia district last Saturday, bringing as return freight 18 tons of old coatings. He informs us that the camp is quite lively. The Leopard mill is running and the furnace is in full blast. The mines are looking well, and some of the principal companies paid their men last week. Everybody in the camp feels confident that the dull times in that section are over, and they anticipate a bright future.

ELY DISTRICT.

LOCAL NOTES.—Pioche *Record*, 23: The amount of bullion shipped by Wells, Fargo & Co., during the past week was $10,183, a decrease of $3,000 on the previous week. The mill of the Raymond & Ely will probably start up on the 25th or 26th. In the mine the same work continues; the pump is run at the usual speed, keeping the water at the same level; still but little benefit will be derived from the running of this pump until the new and powerful pumping machinery of the Meadow Valley is in active operation and working well to assist in taking out the water, so that the explorations in this mine can be pushed downward below the present level. In the Meadow Valley the engines are being put down; a gallows frame also is being erected. Chloriding going on as usual in the mine. The American Flag's main shaft has advanced in depth about a foot a day for the past week. The main shaft of the Pioche mine is also being pushed ahead as rapidly as possible and are now working in quartzite. The Alps mill keeps busily employed running on custom ore and ore from the mine. The mill is running out some fine bullion. A new rope for the mine arrived during the past week, so that no difficulty will now be experienced in hoisting the ore. The same number of hands continue at work on the Washington & Creole, hoisting nearly three tons of ore daily. The usual work of extracting ore continues in the Hahn & Hunt. Nothing being done at present with the Newark. A change was made in the board of trustees during the past week. The building of the smelting furnaces by the citizens, is still under discussion, about $4,500 having been subscribed, with which amount it is proposed to organize and sell stock to make up the necessary balance. A meeting will be held for this purpose tomorrow evening, at 8 o'clock, at the house of Protection hose company. The building of this furnace will be the only salvation for Pioche, until such time as the Meadow Valley and Raymond & Ely can push their explorations below the water level.

EUREKA DISTRICT.

THE BEAT MINE.—Eureka *Sentinel*, July 22: Probably the best mine in the State to-day is the Richmond of this district. The ore on the lower levels is not only rich but abundant. In all of the metals, gold, silver and lead, it carries greater value than ever before. Persons who have lately been through the mine assure us that it is the greatest mining property in the world.

BONANZA.—We understand that Col. Robbins is about bonding the Antelope, Kit Carson and New Law mines for the Chicago market. The aggregate sum to be paid amounts to about $10,000. The Colonel expects to make the turn in 90 days. The mines are all valuable and each for itself shows up well.

RUBY HILL.—Work has been resumed at the ninth level of the Eureka Consolidated, the water having abated. There are good prospects ahead, and, from appearances, not very far ahead either. Work has been considerably retarded at the E. K. on account of the closing together of the bottom of the shaft. When the water was taken out the pressure from the outside was so great as to cause the sides to close in to such an extent as to prevent the working of the large tank which was formerly used for hoisting the water. A smaller one had to be substituted, and of course the work of clearing the mine of water progresses with proportionately less rapidity. Quite an accident occurred at the E. K., Tuesday night, which would have resulted seriously if there had been any one in the shaft. The large wire cable used in the south compartment unwound entirely from the reel and dropped down the shaft without doing any damage.

HUMBOLDT DISTRICT.

BYRON AND PALACE MINES.—Cor. *Silver State*, July 25: The Byron is looking exceedingly well; the vein is about two feet wide and the ore very rich in gold, with some silver. It is beyond doubt the richest mine yet found in this part of the country. Samples of the ore, in which no gold is visible to the naked eye, assay $4,000 or $5,000 per ton. The owners are running a drift on the lead, and are now some 75 feet from the surface. The Palace ledge, which is situated on the north side of Humboldt canyon, is also prospecting very well. The ore in this lead is principally silver. Four samples assayed at the reduction works yielded as follows: No. 1, $1,190 26; 2, $1,041 73; 3, $224 62; 4, $76 26. These samples embraced the different varieties of ores found in the lead and were an average of each kind.

JERSEY DISTRICT.

ON THE MEND.—*Silver State*, July 31: S. J. Chambers arrived to-day from Jersey. He says times are on the mend in that district. The working force in the mine has been increased, and there are now 30 men at work. The Jersey company talk of erecting a concentrator, that being considered a more economical and cheaper method of treating the ore than smelting.

REESE RIVER DISTRICT.

A SIX MONTH FOR BULLION.—*Reese River Reveille*, July 26: The shipment of bullion for the present month by the Manhattan company is the largest ever made during any one month since the discovery of this district. Shipments to date aggregate $200,180, and there are still five days for production and the clean-up left in the month. The shipment of this amount of bullion is quite positive in support of the statement made by the *Reveille* that the mines of Lander hill are now better than ever before since their discovery. For many years they have poured out a steady stream of silver, but have never before given such promise for the future, nor shown such rich and extensive ore bodies for the present as they do now. Austin is obscure and isolated, but she is sure to make herself known abroad by the steady and fruitful production of silver which is assured for years to come. The mines of the Manhattan company, though they have been worked for so long a period, are to-day as good as virgin ground, and mining in them is just commencing in earnest. Heretofore it has been comparatively but mere scratching of the ground.

SPANISH BELT DISTRICT.

QUICKSILVER.—Pioche *Record*, July 22: A rumor comes from Spanish Belt district of the recent discovery of a quicksilver mine. The find is situated between Barcelona City and the Mariposa mine, about seven miles southwest from Belmont. There are, however, conflicting opinions as to the ore being cinnabar, though it is claimed that cinnabar experts have made assays and obtained large yields in quick-liver. The ore is of a reddish cast, but not as high a color as usual for that class of ore. Anyway, for miles the country has been staked off, and great excitement prevails among the inhabitants of that district.

TRINITY DISTRICT.

WORK RESUMED.—*Silver State*, July 22: Work has been resumed on one of the mines in old Trinity district, and the prospects of its being a good mine are very fair. The district, which boasted of having a mill in the early days of the Humboldt, and produced thousands of dollars in gold and silver bullion, has been abandoned for at least eight years. It is situated about eight miles west of Creana.

WARD DISTRICT.

PROSPEROUS.—White Pine *News*, July 20: Just now this young and prosperous mining camp is attracting much attention. New mills are being put up and several furnaces are already completed. From some of our business men who have just returned from there we learn that the camp is lively, and high hopes are entertained of its permanency.

WHITE PINE DISTRICT.

PERSONAL.—White Pine *News*, July 29: During the past week personal movements have been made as follows: Capt. Drake, superintendent of the Eberhardt and Aurora mines, left Wednesday for San Francisco on business for his company, the depreciation of silver having much to do with his visit. Mr. W. H. Gauley, one of the largest stockholders in the Ward district mines, passed through on Wednesday last for San Francisco. He informs us that his company had purchased the 20-stamp mill at Troy mining district. Perley Rowell, foreman of the Eberhardt and Aurora company's mill, was in town on Wednesday. He informs us that the mill is running nicely, and that the silver is flowing out in great amounts.

MILL SOLD.—The English company's mill at Troy, in this county, has been sold to the Martin White company, of Ward, for the low price of $11,000, and is now being removed to that company's mines.

WASHOE DISTRICT.

ROCK ISLAND.—Gold Hill *News*, July 27: The flow of water on the 850-ft level is still strong, requiring a steady use of the pumps to keep it down to permit work on the 850-ft level. The drifts on that level have all been repaired, and work in the face of the drifts, both north and south, resumed.

JUNCTION.—Daily yield, 70 tons of ore. The ore breasts are looking well and yielding finely. The repairs to the Sherman mill are completed, and it is again crushing ore from the mine. The east cross-cuts on the 900-ft level are showing more favorable every day. The north and south drifts on the 1000-ft level are also showing some fine ore prospects.

NEW YORK.—Work has been resumed at all points on the lower levels of the mine. The determination of the present management appears to be only to develop a paying mine, and they are undoubtedly starting out in the right way to do it.

NIAGARA.—Sinking the main incline shaft is making splendid progress. It is now down 405 feet. Indications at the bottom still continue of a favorable character.

AMAZON AND GLASGOW.—Sinking the combination shaft is making splendid progress, the bottom still in good blasting ground.

KOSSUTH.—The main drift on the 360-ft level is showing better and better as it advances to the south

ward. The prospecting drifts on the 500-ft level are being put in excellent shape to do a big amount of cross-cutting in a very short time.

SUPERIOR.—The pumps are at work in good earnest and keep down the strong flow of water. The sinking is going ahead lively, the bottom of the shaft being in very favorable ledge matter.

BELCHER.—Daily yield, 300 tons of ore. The ore breasts and stopes are still showing quite favorably.

WEST BELCHER.—The opening drifts are being pressed ahead at a lively rate. The new ore dump is completed, and the extraction of ore will be commenced in a very short time. The breasts of ore are from 20 to 40 feet in width and show well.

BULLION.—Nothing is yet doing in the Alpha drift, on account of bad air.

LADY BRYAN.—The foundations are fast approaching completion. A portion of the new and powerful pumping machinery has already been shipped from the foundry in San Francisco.

UTAH.—Owing to an accident to the hoisting machinery, but slow progress has been made with the sinking during the past two or three days.

SUCCOR.—The old pumps and rods have been taken from the shaft; the old machinery has been torn out and the deep excavations for the reception of the new powerful pumping machinery is fast approaching completion.

CON. VIRGINIA.—Sinking and raising up on the shaft between the 1500 and 1550-ft levels is making good progress. It will take a week or ten days yet to finish the shaft ready for work. The amount of ore extracted is still limited by the other uses of the shaft, although the introduction of most of the timbers through the drift connecting the 1500-ft level with the C. & C. shaft is making a very favorable diversion in favor of a greater amount of ore extraction. The prospecting drifts in the southern portion of the mine are showing a much better extension of the ore body in that direction than has heretofore been expected. On the 1700-ft level the north drift is still being advanced to connect with the bottom of the south winze. The stories put in circulation that the rise in the stock during the past few days has been caused by the operation of diamond drills on this level, is without any foundation whatever, as there has never yet been a diamond drill used in that portion of the mine. The new amalgamating mill is fast approaching completion.

SAVAGE.—The new pumping engine is completed, ready to attach the pumping rod and commence the hoisting of water. The putting in of the pumping rods, pump columns and pumps is progressing as fast as it is possible for such work to be done. The flood of water has decreased several feet during the past few days from some cause; just what the cause is, is yet hard to tell.

CALIFORNIA.—Daily yield, 700 tons of ore, keeping the mills running up to their full working capacities. The yield of bullion up to the present date is nearly $400,000 in excess of the yield at the same date in June. The ore breasts are looking well, and are yielding finely as usual. The different points at which the ore is being extracted on the 1600 and 1600-ft levels show no material change. The machinery at the C. & C. shaft is repaired, and will be in readiness to commence pumping water by 6 o'clock or 7 o'clock this evening. The new battery mill east of the C. & C. shaft is fast approaching completion.

OPHIR.—Daily yield, 300 tons of ore. The ore breasts both north and south on the 1500-ft level are showing splendidly. The mills are kept running up to their full crushing capacities, and the yield of bullion for this month will not vary much from what it was last month. Raising up and sinking the main incline is being pressed ahead with all possible vigor, the work being driven ahead at three different points. The north drift on the 1600-ft level has nearly reached the north line, at which point a cross-cut has been started to the northwest to cut and prospect the main ledge.

YELLOW JACKET.—The north drift from the east winze on the 2040-ft level is in 42 feet. The south drift from the north winze on the same level is in 28 feet, the two drifts having 69 feet yet to penetrate to complete a connection. Both drifts are perfectly dry, and the face of each is in soft green porphyry. As soon as the connection of the winzes is completed and ventilation obtained, a cross drift will be started east from the bottom of the east winze; a drift will also be started south from the same point. The lateral drifts on the 1740-ft level have been connected and preparations are now being made to start the cross drifts.

SIERRA NEVADA.—The stations and drifts on lower levels at the old shaft are being thoroughly timbered and secured, preparatory to abandoning permanently the operations at that point. This is being done on account of the inefficiency of the old machinary to prosecute the sinking to a greater depth. At the new shaft a station is now being opened at the 1700-ft level. As soon as the station is completed, drifts will be started to cross-cut and prospect the ledge at that point.

PHIL. SHERIDAN.—Sinking the shaft is going steadily ahead, the bottom in good working ground and the sinking making splendid progress.

JULIA.—The hob-pit on the 1700-ft level is about completed. The main south drift on the 1600-ft level is steadily advancing, the face still in quartz and low grade ore, which shows a steady improvement. The main southwest drift on the 1800-ft level is being driven forward, the quartz in the face being much more compact and solid than for some time past.

IMPERIAL CONSOLIDATED.—The north drift on the 2000-ft level is steadily advancing to the northward to connect with the Alpha drift. The north drift from this winze, 100 feet below the 200-ft level, is showing very favorable.

CROWN POINT.—Sinking the main incline below the 1700-ft level is going steadily forward. The main south drift on the 1700-ft level has been pushed forward to the south line without making any valuable ore developments. It is now being continued in Belcher ground to connect with the bottom of the combination air shaft.

OVERMAN.—Sinking the shaft is going steadily forward, the bottom still in very hard blasting rock. The north and south prospecting drifts on the 1200-ft level are steadily advancing.

CHOLLAR-POTOSI.—Sinking the main incline is going steadily forward about 18 feet per week. The old ore stopes are still yielding about 76 tons of ore daily. The assay value of the ore is $33 per ton. Sinking the combination shaft is making splendid progress.

GOULD & CURRY.—Repairing the shaft is going steadily forward. There are yet no new prospecting operations commenced on the lower levels; a few tons of ore is hoisted for the Consolidated Virginia between times when the shaft is not in use for other purposes. The exhaust air fan is working admirably. The erection of the new machinery is steadily advancing. The combination winze now being sunk on the Savage line on the 1600-ft level is now down 210 feet below that level, the bottom still being in perfectly dry ground, although it is nearly 100 feet deeper than the level of the water in the Savage shaft.

FLORIDA.—Face of north drift at the 400-ft level shows considerable improvement, very promising streaks of quartz coming in. The drift is now turned in a westerly direction so as to cross-cut the vein, and is liable to make some interesting developments before long. Water decreasing.

MEXICAN.—Two cross-cuts have been started in a northwesterly direction to cut the ore vein. One of these is on the 1600-ft level and the other on the 1465-ft level, and both are near the north line of the Ophir. On the 1465-ft level the face of the cross-cut is in fine ledge matter, carrying occasional small streaks of ore. On the 1600-ft level the face of the cross-cut is in a very favorable formation.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline is making fair progress, considering the strong flow of water at the bottom. Tha pumps handle the water with ease, but the flow considerably impedes the progress of sinking.

SUTRO TUNNEL.—Face of header in hard working porphyry, with streaks of quartz and clay. The Burleigh and Ingersoll drills make very fair progress in this material, although it is more difficult to work than harder and more compact rock met with heretofore. Total length of tunnel last evening, 13,742 feet.

EAST JUSTICE.—Good progress is being made in the sinking of the shaft, the rock is becoming softer and works to good advantage. A streak of soft brownish quartz, six inches in width, running north and south, has been met with during the past few days in the bottom of the shaft.

WARD.—Sinking the shaft is going ahead at the rapid rate of five feet per day. It is now down 340 feet. The south drift of the Julia is rapidly approaching the Ward line, the face in quartz and low grade ore.

LADY WASHINGTON.—Sinking the main shaft about two and a half feet per day. The bottom is now in the most favorable looking material yet encountered.

HALE & NORCROSS.—The pumps and pump columns are all in place in the shaft, and the rods are now being lowered into position. The pumping engine is in place.

ALABAMA.—Sinking the shaft is going rapidly forward, the bottom still in splendid blasting ground.

ALTA.—The erection of the new machinery is steadily approaching completion.

DAYTON.—The water at the bottom of the shaft is still giving considerable trouble.

PROSPECT.—Total depth of shaft, 421 feet. Material at bottom somewhat softer, composed of porphyry with considerable red jasper and streaks of white quartz.

NORTH CARSON.—The mine is showing well at all developing points, and more good ore is being encountered.

NORTH CON. VIRGINIA.—The erection of the new pumping machinery is going rapidly ahead. The drain tunnel is steadily advancing.

TAHOE.—Sinking the joint shaft on the Lady Bryan line is going rapidly forward, the bottom still in soft working ground.

CALEDONIA.—The flow of water is still strong in the shaft and greatly impedes the progress of sinking.

EUROPA.—North drift on the 600-ft level is showing a fine streak of quartz with some clay.

TWIN PEAKS.—Sinking the new working shaft will be commenced in a few days.

HERALD.—Sinking the shaft is going forward, the bottom still in soft ledge matter mixed with quartz and streaks of very rich ore.

COSMOPOLITAN.—Considerable pay ore coming from the north drifts. Ventilation of mine perfect, allowing of excellent work being done.

NEVADA.—Face of west drift in low grade ore. No signs of west wall as yet.

(Continued on Page 100.)

The Lixiviation Process for Silver Ores.

Mr. Henry S. Brooks, who has had great experience with the above process in Mexico, writes as follows concerning it to the *Bulletin*:

The reduction of rebellious silver ores by lixiviation, instead of by amalgamation, is now almost in universal use in Sonora, Mexico, and Lower California, and is rapidly gaining favor in Sinaloa and the interior. It is not, as many suppose, a new discovery, but merely a modification of an old and well known process, with cheaper chemicals than those formerly in use.

The Method at Present Adopted

Is to crush dry through a No. 18 or 20 screen, then treat in reverberatory furnaces with salt in exactly the same way as for amalgamation. The ore should be more carefully chloridized, if possible, than for treatment with quicksilver. When thus prepared the ore is placed in large tubes or vats with false bottoms covered with canvas or burlaps. The vats hold about six or seven tons. The ore is then leached or lixiviated with water for a few hours to dissolve and carry off the soluble salts of the base metals. The salts of silver not being soluble in water are not affected by this process. After the base metals are thus eliminated the ore is leached with a solution of hyposulphite of soda, in which the silver *is* soluble. This lixiviation takes from six to ten hours, or even more, according to the richness of the ore and the strength of the solution. This solution is carried to a large vat. It is transparent, and scarcely distinguished from common water, except by its taste. The silver thus obtained in solution is precipitated by a polysulphide of lime, which is prepared by boiling sulphur and lime, proportioned according to the metals under treatment. This solution can be boiled either by fire or steam. A portion of the sulphur and lime solution is then added to the hyposulphite of soda solution when the silver is at once precipitated as a black powder, which is sulphide of silver, SAG. After straining, this sulphide is roasted in a reverberatory furnace to expel the sulphur, during which process it granulates, assuming much the appearance and color of blasting powder. In this condition it will assay from five to six hundred fine. It is then refined in a refining furnace, or in the crucible, according to the quantity under treatment.

Its Economy

Is very great. A skillful operator will work up to 95 per cent. of the assay. The ordinary average loss by amalgamation is at least 15 per cent., making a gain of 10 per cent. All the wear and tear, as well as the original outlay for pans or barrels is avoided, and no power whatever is requisite. The vats can be built for a mere trifle, and will last an indefinite length of time. Hyposulphite of soda is worth in this market from five to six cents per pound, sulphur from four to five cents, while lime is abundant in nearly every mining district. In the hacienda managed by the undersigned, producing, say, $60,000 a month, the following saving is effected:

Eight per cent. say, additional product	$ 4,800
Two per cent. less duties, the silver being 970 fine instead of 750	1,200
Four cords of wood less per diem, at $7.50 per cord	900
Saving in use of quicksilver	1,000
Saving in labor	250
Wear and tear of machinery	500
Additional gold saved, at least	1,600
Making a direct saving per month of	$10,120

But in addition to this we use a No. 20 screen instead of No. 40, as in the amalgamation process, thus more than doubling the power of the battery. Experience proves that crushing with an 18 or 20 screen expedites the lixiviation process without producing any additional loss. In addition to all these items, the first cost of building a mill is greatly reduced.

Ores Suitable for Treatment by Lixiviation

All rebellious ores not containing free gold can be advantageously treated. It has been urged as an objection, even by parties acquainted with the process, that the proportion of gold frequently found in silver ores cannot be saved by lixiviation. Our experience is decidedly to the contrary. It is true our ores have but very little gold, varying from a trace only to five or six dollars a ton. By the process of amalgamation this yields, in a bar of 1,500 ounces, only about $20 gold. By lixivation we obtain $100 and upward in each bar.

It is the opinion of those having the greatest practical experience as well as scientific knowledge, that there are no ores so base, no combinations so stubborn, but they can be treated successfully—say to within 90 per cent. of the assay, by lixiviation. Of course there is much to learn in a process new at least in its application to the economical treatment of ores in large quantities; but I have not as yet heard of any failure where ordinary intelligence has not been wanting; while on the other hand the use of quicksilver has been almost entirely if not entirely abolished in Sonora. I should add that the process is now used frequently without even the use of soda, with sulphur and lime only. By this method the treatment is somewhat slower, and is said not to save the gold, at least not to an equal extent, but it is even more economical. Although the process appears so simple I should strongly recommend any person without experience to employ a skillful man. They are plenty in Sonora.

Other Questions to be Considered.

Of almost equal importance is the question of chlorination. Where labor is so high as it is in California and Nevada, it is ruinous to treat ores in the old reverberatory furnace, employing three eight-hour watches to chloridize a ton and a half of ore. The economy of fuel, too, is becoming of paramount importance. The Stetsfeldt furnace has been very successful in Nevada under skillful management, but in Mexico it has in every instance proved a failure. If it were not for the fact that an unusual number of very able and experienced men are engaged in mining in Mexico, one would not be inclined to attribute the failure to a want of merit in the furnace. It is probable, however, that the Mexican ores, being so excessively rebellious, are not sufficiently chlorinized by falling down the shaft and the subsequent roasting. I have been informed, though, that Mr. Stetefeldt has made several important improvements of late, including an antomatic discharge, rendering the furnace suitable for any class of ores. For my own part, I have very little doubt but that the Stetsfeldt furnace can be successfully used anywhere—perhaps with some slight modifications.

A new furnace, at present but very little known, is the "White furnace," a working model of which can be seen at the Ætna foundry. It is very simple, economical in the extreme, and not liable to get out of order. It is probable that some unimportant modification of this also might be required for some ores, such as changing the position of the upper flues, etc., but it is worthy the careful attention of all practical mill-men.

A very large proportion of the wealth of the Pacific States is to be found in the abundant veins containing ores of a more or less rebellious character, for the successful treatment of which improved methods of reduction are necessary. There are few questions of greater importance at the present time, with silver at such an enormous discount, and all our industries so seriously depressed thereby.

CONSUMPTION OF WOOD ON THE COMSTOCK AND VICINITY.—The consumption of wood on the Comstock and in mills and other works connected with the mines will be, for 1876, about 260,000 cords, worth, at $12 per cord, $3 120,000. Of this 200,000 cords will be shipped by rail, 20,000 by the Carson river to its destination and 20,000 cords will be taken out of the river at points between Empire City and Dayton and hauled by teams to mines and mills. To this must be added 20,000 cords consumed by the locomotives of the Virginia & Truckee railroad. About 180,000 cords of wood will be delivered by flumes between Genoa and Reno on the line of the railroad and branch tracks. The amount of wood sent down from the mountains through the flumes has been yearly increasing, while the amount of wood floated down the Carson river is steadily decreasing. The amount of wood floated down the river in 1874 was 140,000 cords; in 1875 it was 75,000, and this year, all told, it will not exceed 60,000. The reason of the decrease of the amount coming down the river is owing to the fact that the pine forests are each year cleared off to a greater distance from the stream and its tributaries. Eventually the standing forest trees remaining will be at such a distance from the river that it will be cheaper to build flumes through which to send down the wood than to haul it to the stream and then drive it. It is estimated that the amount of lumber and mining timbers which will be shipped to the Comstock during the year will be between 90,000,000 and 95,000,000, feet. Nearly all of this will come by rail.—*Virginia Enterprise.*

A New Fungus on the Pine Trees.

Dr. H. W. Harkness, who is devoting the summer to scientific studies in the eastern counties of the State, has discovered a new fungus on the young pine trees, which promises to harm the trees and of which our readers should be forewarned. In a communication to the San Francisco microscopical society, Dr. Harkness writes as follows: I have to-day forwarded for the society's cabinet a specimen of *Peridermium*, a fungus which is attacking the small pine trees in the vicinity of Colfax, at which point Mr. Moore and myself discovered it on the 26th of May last. On the 20th inst. I again visited the locality for the purpose of noting the changes which had occurred during this interval. The fungus belongs to the genus *Peridermium*, order *Æcidacie*, and appears both on the limbs and trunks of young trees of the variety *Pinus Ponderosa*, generally forming a complete circle around the tree, its sporidia appearing as a zone of bright orange yellow. The spaces first germinate beneath the cuticle, which it destroys. Owing to the irritation of this presence, an abnormal thickness of the cambium is produced, which, in turn, gives place to an excessive growth of wooly fiber. This process being repeated from time to time, a large bulbous expansion is soon formed, so that, as often occurs, a stem of but an inch in diameter is enlarged to that of four or five. Above this bulb the further development of the stem is retarded or arrested altogether, its place being supplied by a dense tuft of minute branches.

As no reference to this fungus is found in any of the books at my command, I am inclined to the belief that it is a new variety. Yesterday I received a letter from Prof. W. G. Farlow, of Cambridge, Mass., in which he says: "I send you a specimen of *Peridermium*, which is attacking the *Pinus Ponderosa* of this vicinity. Do you find it in California?" As the specimen sent by the Professor agrees in every essential particular with the one sent to this society, it would appear that the fungus is attacking the forests in the Eastern as well as the Western portion of the United States. But one other variety of *Peridermium* is yet known upon this coast, and that is found upon the foliage of the *Pinus Insignis*, growing in the Golden Gate park, San Francisco, in the month of January last. This variety we then identified as *P. Pini*, which so far has not produced any special damage.

In the vicinity of Colfax the fungus appears to be limited to an area of but a few acres in extent. Within that area, however, it is destroying the young growth, and should it become generally disseminated, it bids fair to do great harm to the timber trees of this coast.

The North Wind.

At a late meeting of the Agassiz Institute, of Sacramento, J. H. C. Bonte submitted a long essay on the hot, dry north wind, which frequently does serious damage in the Sacramento-San Joaquin valley in the summer. This wind evaporates an inch of water in 24 hours, at Sacramento, and still more at the ends of the valley, bakes fruit on the trees, chars tender leaves, kills buds or sprouts of cherry and peach trees, cuts down young orange trees like frost, sometimes kills old apple trees, blights and ruins wheat when in the milk, kills young turkeys and chickens, affects cows so that they give one-third less milk than usually, weakens horses so that they do not travel well, and has a depressing and irritating effect on the nervous system of man. It is sometimes called the "poison wind." Such a wind prevailed on Monday and Tuesday, the 26th and 27th of June last, and on the latter day the following temperatures were observed:

Towns.	Temperature. 7 A. M.	12 M.	9 P. M.	Lat.
Redding	84	104	90	40.35
Red Bluff	88	113	94	40.12
Tehama	84	110	100	40.00
Chico	76	111	85	39.40
Marysville	83	96	92	39.10
Sacramento	65	98	76	38.30
Stockton	70	96	89	37.56
Modesto	80	103	82	37.40
Merced	80	104	89	37.20
Goshen	78	111	73	36.20
Delano	81	103	92	35.50
Sumner		101	89	36.35
San Francisco	64	76	66	37.40

The latitudes are guessed at from a common map, and are not exact. The towns, save San Francisco, are all in the Sacramento-San Joaquin valley, on the line of its railroad, about 90 miles on the average from the ocean—none more than 100 and none less than 70. It will be observed that the heat is greater near the ends of the valley than in the center, which is cooled by the ocean breezes blowing in through the Golden Gate. Delano and Sumner are cooler than Merced, because they are south of Tulare lake, the evaporation from which reduces the heat of the atmosphere.

Mr. Bonte argues that while the north wind does much harm it also preserves man from many diseases, and protects grain from pernicious fungi. The planting of trees through the valley, by protecting the soil against the sun, preventing the early evaporation of the moisture from the winter rains, and checking the force of the wind on the surface, will have a tendency in time to reduce its influence in the future; and irrigation, by diminishing the heat and consequent rarification, will contribute also to the same result.—*Alta.*

A FINE bell metal consists of 71 parts copper, two zinc, and one iron.—*Scientific American.*

Spanish Dry Diggings, El Dorado County.

Spanish Dry Diggings, says a correspondent of the El Dorado *Republican*, is situated in the northern part of El Dorado county, on the summit of the hill above the Middle fork of the American river, five miles from Georgstown and four miles from Greenwood. Spanish bar, El Doradn Slide, Dutch bar, Rocky Chucky, Canyon creek and other noted localities of the early mining days are within a short distance.

In 1848 Don Andreas Pico, brother of ex-Governor Plo Pico, organized a company of Mexican miners, chiefly Sonoranians, for the purpose of a prospecting tour through the Sierras, to test the extent of Marshall's discovery of gold. The company thus organized under the leadership of Don Andreas proceeded north to the Yuba river, and from thence south to the Stanislaus, traversing and superficially prospecting all the since celebrated central mineral belt, known to the world as California's richest placer diggings. In the course of his trip Don Andreas passed through what is now known as Spanish Dry Diggings. Resting a short time here, the most experienced of his men, detailed for prospecting, were at work in the ravines, obtaining rich prospects in course gold of a quartz nature.

In 1849, the report of Don Andreas having become generally known among the Mexicans, others of that nationality became in many instances the pioneers in mining settlements. It was thus here. The first settlers were of Spanish-American origin. Soon after came Americans, Germans and others. The name of the first trading-post or permanent settlement was Dutchtown, after which the name of the village was changed to correspond with that by which the mines in the vicinity were known, and thus came the name of "Spanish Dry Diggings."

In 1855 the first quartz-seam diggings were discovered here, which has since resulted in the development and working of many valuable mines, the most celebrated of which are the Grit, Barr, Short Handle, Cherry Hill, Summit, Davis, Taylor, and others of less note. The amount of gold taken from these claims has been very large, the best authority here estimating the Grit and Barr claims alone to have yielded $500,000 and $300,000 respectively, and the others named many thousands each.

Our location is pleasant, degrees of heat and cold seldom approaching an extreme. Our population approximates 100, with comfortable residences, and surroundings which compare favorably with those of our sister villages throughout the county. Like our neighbors, we have a sense of local pride in our mines, our school, the honor and integrity of our people, etc., but if driven to the wall we invariably fall back on our mines, and instance the large and beautiful nugget of gold taken from the Grit claim in 1865, a nugget weighing 16 pounds, which if broken in small pieces would have presented a beautiful specimen in each and every one of them.

Aside from our seam-diggings we have also the celebrated Sliger quartz claim, a true and well defined quartz lode, owned and worked by Messrs. Hunter, Wade, Roush, Simpers, Hines and Grinnell, a claim undoubtedly among the best in the county, if not also in the State. The owners are content to themselves quietly work their claim without the aid of outside capital, which fact of itself is its best recommendation.

About one mile north of the Sliger mine, and on the same lode, is the claim of Messrs. Hines & Co., worked continuously and profitably.

From the character of our mines and their extent, a practical miner, although a stranger, could not fail to pronounce the chances for the future as favorable as in the past. On the second Centennial of American independence the writer hopes and confidently believes that mining will be profitably and extensively carried on in what is now known as the northern portion of El Dorado county.

ENGLISH STEEL IN OUR MARKET.—The *British Trade Journal* says: It is no longer possible to disguise the fact that English steel has had its best day in the American market. Everything points to that conclusion, and our consul, writing from San Francisco, says "it is only a matter of time when the foreign manufactured article will cease to be imported. Large consumers of steel are using American in the manufacture of axes, chisels, scythes and edge tools generally, and hammers and sledges."

TO JOIN LEAD PLATES.—The joints of lead plates may be made as follows: The edges are brought together, hammered down into a channel cut out of wood, and secured with a few tacks. The hollow is then scraped clean with a scraper, rubbed over with tallow, and a stream of hot lead is poured into it, the surface being afterwards smoothed with a red hot plumber's iron.

THE project of building a bed-rock flume from Klamath river to Cottonwood creek, Siskiyou county, has had to be abandoned, on account of insufficient fall for the flume. The ground which it was intended to work is immensely rich, but has only been worked superficially, owing to the difficulty of draining it.

THE deepest Atlantic soundings ever made were 3,875 fathoms, 90 miles north of the island of St. Thomas. The pressure at this depth broke the bulbs, which were made to stand a pressure of three tons.

USEFUL INFORMATION.

Hints for Thought and Practice.

The following are useful memoranda for hydraulic calculations: 1 cubic foot of water = 62.425 pounds; 1 cubic inch of water = 0.03612 pounds; 1 gallon = 10 pounds, or 0.16 cubic foot. The pressure of water per square inch in pounds = the head in feet multiplied by 0.4335. Sea water = 1.027 weight of fresh water, or 64.11 pounds per cubic foot.

As the result of very many experiments, Professor Kick recommends the following solution for engraving iron and steel, to show the grain, etc.: Equal parts of hydrochloric acid and water, with a trace of antimonial chloride.

Camphorated oil is highly recommended as a furniture polish. This is simply sweet oil in which gum camphor is dissolved. The camphor serves an additional purpose of driving away moths.

An ordinary boiler furnace requires 300 cubic feet of air for the consumption of each pound of coal. From 13 to 20 pounds of coal may be consumed per superficial foot of fire grate. Three-quarters of a foot of fire grate are required to evaporate a cubic foot of water.

The bindings of books may be preserved from mildew by brushing them over with spirits of wine. A few drops of any perfumed oil will secure libraries from the consuming effects of mold and damp. Russia leather, which is perfumed with the tar of the birch tree, never molds or sustains injury from damp. The Romans used oil of cedar to preserve valuable manuscripts. Russia leather covered hooks, placed in a stationer's window, will destroy flies and other insects.

To make fly-paper: Dissolve, in one gallon of warm water, one ounce of arsenic and half a pound of lump sugar, in which steep sheets of white filtering paper for a few moments, until they are thoroughly saturated, during which time the solution should be kept agitated. Then hang the sheets on lines, and when dry, cut up into pieces of convenient size for sale. When required for use, place them in shallow plates or saucers, and moisten by pouring on them just as much water as they will absorb. They will be found to attract and instantaneously kill flies, wasps, gnats, mosquitoes and similar insects.

The actual horse power of pumping engines = quantity of water raised per minute in cubic feet multiplied by hight elevated in feet, multiplied by 0.0023. The indicated horse power of engines is found by dividing twice the product of the area of the piston in square inches multiplied by the average pressure of steam in pounds per square inch in cylinder multiplied by the number of revolutions per second multiplied by the length of the stroke in feet by 550.

Useful numbers for pumps: The square of the diameter multiplied by the stroke, multiplied by 0.7854, gives capacity of the pump cylinder in cubic inches; by 0.002833, in gallons; by 0.0004545, in cubic feet; by 0.02833, in pounds fresh water.

Resistance in pounds per ton on different roads, exclusive of the gravity: Stone tramway, 20; paved roads, 33; macadamized roads, 44 to 67; gravel, 150; soft sandy and gravelly ground, 210.

The following are the ordinary dimensions of windmill sails: Length of whip, 30 feet; breadth at base, 12 inches; depth at base, 9 inches; breadth at tip, 6 inches; depth at tip, 4½ inches. The effective horse power is found by dividing the product of the total area of sails in square feet and the cube of the velocity in feet per second of the wind by 1,080,000.

FRENCH VEGETABLE LEATHER.—A material invented by M. Gollissaint Voneche, of Paris, has recently made its appearance on the German market, which goes by the name of French vegetable leather, and which is manufactured in the following manner: A wadding of wool waste, or even of wool itself, of uniform thickness, is laid upon a hot polished zinc plate, and a concentrated decoction of *Fucus crispus*, or pearl moss, or any other fucus-like material, poured over it, and then it is pressed down between two rollers which are placed at a distance between each other corresponding with the intending thickness of the leather; after being rolled, it receives a coat of boiling linseed oil, and is then dried; lastly, the dried sheet receives a thin coating of vegetable wax, and, in order to make it supple, it is once more rolled between hot chamfered rollers. In order to produce a cheap substitute for sole leather, the slimy decoction is largely mixed with flock-wool until a thick pap is formed; this is spread over zinc plates and covered on each side with a thin layer of wool waste, then dried, and afterwards coated with boiling linseed oil, being lastly subjected to a heavy pressure between zinc plates in a hydraulic press.—*Ironmonger.*

THE CONVEYANCE OF EXPLOSIVES.—Revised regulations for the conveyance of gunpowder, gun-cotton and explosives generally, have been issued to the British army. As an ordinary rule, the gunpowder, small arm ammunition and other explosives will be sent by contract. Carriers, and articles so conveyed, when they leave the ordnance store department, and until they reach their destination, will be under civil custody. Care is therefore to be taken by the officers making issues that proper packages are used. On an emergency explosives may be conveyed under the Secretary of State's warrant in charge of a conductor, in which case precautions of a very special character are enjoined. One of the new rules is that gunpowder and gun ammunition may be sent together, but never with other explosives. Gun-cotton may accompany small arm ammunition, but filled shells and war rockets will be sent separately from either. Specific orders are given against smoking and against the possession of lucifer matches by any one employed in the conveyance of explosives.

Alloys to Resist Incrustation.

Oliver Holden, of Chicago, writes for the *Scientific American Supplement* an account of some alloys which he employs to resist incrustation: The alloy consists in a compound of zinc, from thirty-three to fifty parts, by weight; tin, thirty-three to fifty parts, by weight; lead, one to ten parts, by weight, and antimony, one to ten parts, by weight. These are combined by melting them together, or by melting separately, and mixing the same, forming a homogeneous metal.

To make a compound of these metals which shall be homogeneous, proper fluxes must be used, and great care exercised in melting, preference always being in favor of a close vessel—as a crucible with cover. First, melt the antimony, keeping the molten metal covered with a flux of powdered borax and resin (each four parts), and one part potash, thoroughly mixed, to which add the lead. Melt the other two metals in separate vessels—the tin first; then add the flux, and then the zinc. When melted stir thoroughly with a stick of white wood. Now, pour the molten antimony and lead into the zinc and tin, stirring the whole thoroughly during the pouring out, keeping the mass covered with the flux to prevent oxidization by exposure to the atmosphere. Different waters require different proportions of the metals.

The rendering of iron electro-negative (and hence preventing its affinity for oxygen) can only be done at some cost or force, but the cost or force required can be regulated by my mixture of metals so perfectly as to make the cost or force almost nothing. To illustrate: When iron is subjected to the action of saline water I would use, zinc, 40 parts by weight; tin, 50 parts; lead, 10 parts; antimony, 5 parts; but, if the same water were above a boiling heat, I would use—zinc, 33 parts; tin, 50 parts; lead and antimony, each one part. In fresh neutral waters I would use—zinc, 50 parts; tin, 33 parts; lead, 10 parts, and antimony, 5 parts. In acidulated water I would use—zinc, 33 parts; tin, 50 parts; lead and antimony, each one part; or in proper proportions to resist the action of the liquid in which they may be placed.

This alloy I attach to the iron at convenient points, somewhat distant from each other, by applying it in the form of rivets or bolts inserted in various portions of the boiler or vessel; or in the shape of rings, bands, or plates, which are hung upon the tubes or flues of the boiler, or otherwise fastened to the structure in any convenient manner.

NEW COVERING FOR THE OUTSIDE OF STEAM BOILERS.—A novel material for jacketing boilers has been introduced by Messrs. A. H. Leenw & Co., of New York. It is composed of cork, and is claimed to have considerable advantages over other materials used for the same purpose in being easily and rapidly applied or removed, preserving boilers exposed to the weather from unequal expansion or contraction, being non-combustible, non-conducting in a high degree, and not affected by the action of steam, heat, or the weather.

GOOD HEALTH.

Poultices and How to Make Them.

A poultice usually is only a desirable vehicle for imparting heat and moisture. By softening the tissues, poultices facilitate the passage of inflammatory products outward. The heat and moisture relax the tissues, and to that degree relieve the tension due to the inflammation, and to that extent relieve pain. The pain can further be eased by adding laudanum and such substances to the surface of contact of the poultice.

The materials best calculated to take up and give out the heat and moisture spoken of, are in common use. There must be enough of the mass to secure and retain enough heat to be of use, and therefore a poultice should be at least an inch thick. To prevent cooling in spreading, the cloth upon which the mass is to be spread should be laid out on a heated plate or dish, and the poultice, with not enough free liquid in it to "drip," rapidly and evenly spread over the muslin. A thin piece of quite old muslin should then be spread over the surface of the poultice, so the mass will not come into immediate contact with the skin. The spread area of the poultice should be just the size required; and the fabric upon which it is spread should extend beyond the edges of the poultice material, so the unspread selvage can be turned over the edges of the mass. This will keep the poultice from leaking away.

After having been applied as warm as can be borne, a piece of oiled silk—or even oiled paper might answer—should be spread outside to retain the moisture, and something outside of that again to keep in the other useful feature of the poultice—the heat.

Such applications must necessarily be removed and renewed every little while. If poulticing is to be done at all, it must be done well, and that is, properly. A few hours of poulticing applied every half hour, will do more good than many hours of poulticing done in the usual way.

BREAD-AND MILK POULTICE.—Remove the crust from the part of a stale bread, and crumble the bread into a bowl. Pour on this enough sweet milk to cover it, and simmer over a fire, stirring it all the while until the bread becomes completely broken up. This poultice is now to be applied to the patient as warm as can be borne.

FLAXSEED POULTICE.—Take of flaxseed meal a sufficient quantity, and pour on it, little by little, enough cold water to make of suitable thickness. Then heat the entire mass. A small piece of lard is sometimes added to keep it from adhering to the part.

YEAST POULTICE.—Mix a pound of linseed meal or oatmeal into half a pint of yeast. Then heat the mixture over a gentle fire, stirring carefully to keep from burning. When it becomes warmed through, it can be spread on linen like any other poultice. Yeast poultices are often ordered by physicians when there is a fœtid discharge from ulceration, which it is supposed to correct.

BREAD-AND-WATER POULTICE.—Take a slice of stale bread, carefully pare away the hard brown crust which lies around the edge, and then dip it into a vessel of hot water; lift it out at once, and if not too hot, apply to the part where it should go.—*Mechanics' Magazine.*

The Manufacture of Doctors.

It is becoming notorious that a Harvard diploma in medicine is the most valuable diploma procurable in this country. The consequence is that the better class of students will seek it, until the other schools adopt the same plan, and do away forever with the present cheap and ineffioient one. A Harvard medical diploma means something; the ordinary diploma means very little, even to those who get it. A Harvard diploma means work, achievement, scholarship, honor, success; and the best material in preparation for the profession will try for it at any sacrifice. The medical schools of New York and Philadelphia must wheel into line with Boston, or be left behind, where they ought to be left. Nothing will be gained to the profession or the world by any other course, or, in the long run, to the schools themselves.

These matters of health and sickness, life and death, are very serious ones, and there are few things more sad—more horrible, indeed—than to see a sick or an injured man in hands utterly incompetent to treat him. The truth is that a physician should be always a first-class man—first-class in his moralities, his character, his acquirements, his skill. No course of education can be too thorough for him, no preparation for the stupendous work of his life too exacting. Medical students are not apt to think of this. By becoming familiar with diseases and death, they are too apt to grow thoughtless, and to forget the preciousness of that possession which they are to be called upon to protect. They certainly will not think of it if their instructors make it easy for them to acquire their profession. The commission of a single unworthy man to practice the profession of medicine is a direct means of demoralization, of which no faculty can afford to be guilty. Let us manufacture no more doctors; let us educate them.—*Dr. J. G. Holland; Scribner for August.*

POISONING FROM ANILINE COLORS.—The *Scientific American* notes the first authenticated case of poisoning by aniline dye, which it says came under its immediate observation. The garments were of a light woolen material, and, having been somewhat worn, were sent to an extensive dyeing and scouring establishment in New York city to be dyed a dark blue. The owner, after wearing the clothes for a few days in hot weather, observed that the blue color stained his undergarments, and in the localities of the stains he became sensible of a cutaneous eruption. The latter soon extended on a large area, which became excessively inflamed; and a pustular state followed, resulting in excruciating suffering and prostration. The case was carefully examined by several eminent physicians of New York city, who pronounced it one of the most severe attacks of poisoning that they had ever encountered, and unhesitatingly ascribed it to the dyeing of the fabric with aniline blue. Had the sufferer been a child or an invalid, the opinion was that the disease was sufficiently malignant to prove fatal. Perhaps the safest rule is to watch all colored goods when worn, and promptly to discard the clothes on the first appearance of the dye's discoloring the garments or person wherever it comes in contact.

ANTIDOTE AGAINST MERCURIAL AND LEAD POISONING.—The Commission des Arts Insalubres is studying the system proposed by M. Melsens for remedying the injurious effects of lead and mercury. Ordinary therapeutics avail little in the numerous cases of injury from the white lead used by painters, or the mercury used in the looking-glass trade. But iodide of potassium taken in draft brings the poisonous metals into a state of solution, in which they are easily removed from the organism.

MINING AND SCIENTIFIC PRESS.

W. B. EWEB.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, GEO. H. STRONG
W. B. EWEB, JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 mos.	12 mos.
Per line.....	.25	.80	$2.00	$5.00
Half inch (1 square)...	$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Four weeks are rated a month.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk

Rates of Subscription.

Secretaries of Grangee and Farmers' Clubs, (and all reliable farmers and enbscribers of the PRESS) are hereby authorized to make up clubs, of five or more names, at $3 each, per annum, in advance.

☞ No Agents or Secretaries are authorized to receive subscriptions at less rates than $4 per annum except in clubs of five or more, strictly cash in advance, yearly subscribers. Any arrearages that may accrue on club subscriptions will be charged at full rates.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, Aug. 5, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A Geological Anomaly, 89. The Lumber Mills, Factories, etc., of Truckee and Vicinity, 93. Our Industrial Exhibition; Gold in Talc-slate; Gems and Precious Stones; Notices of Recent Patents, 96. The Centennial at Philadelphia, 97-100. Aid for Boys and Girls; Patents and Inventions, 101.

ILLUSTRATIONS.—Lime Works in El Dorado Canyon, 89. Main Exhibition Building; Ground Plan of Main Building, 97.

CORRESPONDENCE.—Alpine County—Its Mines and Resources, Past, Present and Future; Centennial Chat, 90. Facts About Peat; Mechanical Ore Concentration and Separation, 100.

MECHANICAL PROGRESS.—English Minting Operations; American Steel; The Railway Operations of 1875; Introducing the Blast; Steel Wire Hawsers vs. Hemp Hawsers; The English Patent Office; A New System of Plastering; Progress in Japan; Carbon Bronze, 91.

SCIENTIFIC PROGRESS.—Effects to Use Solar Heat; Does a Bird Die a Natural Death; Concerning the Visibility of Flames; Prizes for Scientific Writers; The American Chemical Society, 91.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 92.

MINING SUMMARY from various counties in California, Nevada, Oregon, Montana and Idaho, 93-94-100.

USEFUL INFORMATION.—Hints for Thought and Practice; French Vegetable Leather; The Conveyance of Explosives; Alloys to Resist Incrustation; New Covering for the Outside of Steam Boilers, 95.

GOOD HEALTH.—Poulticee and How to Make Them; The Manufacture of Doctors; Poisoning from Aniline Colors; Antidote Against Mercurial and Lead Poisons, 95.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 100 and other pages.

MISCELLANEOUS ARTICLES.—The Working Facilities at the Eureka Consolidated Mine, 90. The Lixiviation Process for Silver Ores; Consumption of Wood on the Comstock and Vicinity; A New Fungus on the Pine Trees; The North Wind, 94. Spanish Dry Diggings, El Dorado County; English Steel in Our Market; To Join Lead Plates, 95.

MINT ITEMS.—On the 1st inst., Mr. Cicott, coiner of the United States mint in this city, delivered to the superintendent the sum of $1,020,000, the largest delivery ever made in one day. General La Grange, the superintendent, with Mr. Cicott and the other officers of the mint, are running it to its fullest capacity, and turning out a large amount of coin monthly. For July, although commencing on the 7th of the month, the coinage was $4,606,000; while the coinage for July, 1875, was $2,508,000, showing an increase of $1,098,000 this year, although not working a full month owing to the Centennial celebration.

HOME-MADE STEAM YACHT.—The Marysville *Appeal*, July 29th, states that a propeller engine was shipped the day before from the Marysville foundry, for a steam yacht to be run on Lake Tahoe, by Messrs. Yerrington & Bliss. The builders guarantee 18 knots an hour. The hull is of steel. Its length, 75 feet over all; beam, 19 feet. It was shipped to Tahoe in sections, and there put together. The boiler is also of steel. The whole was designed by William R. Eckhart, of Marysville foundry.

SAYS the Winnemucca *Silver State*: "A copper ledge has been discovered near Greggsville, in Gold Run district, which is said to be 25 feet wide. The ore is principally red oxide, of which there is a large quantity in sight on the surface. The location is about 17 miles from the railroad, Golconda station being the nearest point."

THE debt statement shows a reduction of $1,138,033. Coin balance, $59,843,684; currency, $12,500,349; coin certificates, $2,931,300; specie deposits for redemption of certificates of deposit, $32,815,000; outstanding legal tenders, $36,919,228.

Our Industrial Exhibition.

Before another issue of the PRESS the great fair of the Mechanics' institute will be under full headway. As far as the managers are concerned all their arrangements are already completed, but exhibitors have not as yet all come in. They are busily engaged, however, in arranging their displays, fixing up their stands, etc. The large engine which furnishes the power for the machinery department, and which was described in our last number, is in perfect running order ready for work. This is the first time, we believe, in the history of our fairs that such was the case, and the Fulton foundry is deserving much credit for being so prompt.

The opening exercises will take place at Wade's opera house, on Tuesday, August 8th. The programme it as follows:

1. Music.....By the Band.
2. Anthem.....By Aimee Chorus.
3. Prayer.....Rev. Dr. Elken Cohen.
4. Chorus.....By 500 pupils from High School.
5. Opening Address....Preet. of Mechanics' Institute.
6. Song.....By Chorus.
7. Poem.....By Hon. Frank Soule.
8. Chorus.....By pupils from High School.
9. Oration.....Henry Edwards, Esq.
10. Grand Chorus.....
11. Tableau...Repreeenting the various tradee at work.

The programme is an interesting one and will be much more enjoyable than usual, as it is carried out in a theater, instead of the pavilion where there is sure to be a great deal of noise on opening day. We understand that Mr. Edwards' oration will be on an industrial subject and we are sure it will be worth listening to. We hope to see a large attendance of all classes of the community, especially of mechanics, who are specially interested. On the same day the exhibition will be open to the public, so that those who have not yet procured season tickets would do well to do so now. Holders of season tickets are admitted to the opening exercises of course.

We shall give a full report of all of interest at the fair during its continuance, selecting especially those things worthy of mention from their novelty. The publishers of this journal will also publish the MECHANICS'-FAIR DAILY, which will be printed at the pavilion every evening and be devoted to the interests of the Eleventh Industrial Exhibition.

Gold in Talc-slate.

The *Mines, Metals, Arts and Railroad Journal*, of St. Louis, under the heading of "Premium Stupidity," says:

A statement of a "discovery of gold in talco-slate" with a prosy "description of the material and its constituents" has been running around, set forth and by some commented on, by nearly every paper in the country devoted either to science or mining. This "wonderful new phase in gold mining" is no new phase at all. Gold bearing slate constitutes nearly one-half of the gold-bearing material of the globe, and as such has been a most productive source of that metal. Most of the placer gold has washed out of the talco-slates. In Siberia, South America, Australia, Africa, Southern United States, etc., gold bearing slates have been long worked, in the case of Africa, for thousands of years. It must be a dry time throughout the craft.

As the item referred to originated in this journal we feel called upon to inform our contemporary that it has the terms "slate" and "talc-slate" somewhat mixed. While it is perfectly correct that gold has been found in slate for centuries, we can assure the learned editor that its discovery in "talc" and the slaty formation of talc in regular well defined ledges, and the method of working the same, is of quite a recent date. We will send our learned friend by mail a specimen of the auriferous talc-slate, which he will acknowledge a novelty, especially if we inform him that the specimen was taken from a 22-foot ledge, which is traceable for miles.

The statement that "it must be a dry time throughout the craft" our contemporary proves conclusively to be the case by taking a three column article on the "Mindeleff Procesa" from this journal without the slightest hint at a credit. An elementary mineralogy would be a good book for *Mines, Metals and Arts* to have in its library.

ABOUT 1,000 workingmen met in Tompkins square, New York, one day last week. They declare that 30,000 men are out of employment in the city, daily searching for work, without success, and are living on the charity of friends and neighbors. They formed in procession, headed by 15 policemen, and marched to the Mayor's office, in the City hall. The long-shoremen struck for an increase of wages, and the police reserves were out to preserve peace.

SAN BENITO *Advance* reports that the Red Rock coal mining company, in Chalome valley, recently struck good bituminous coal in a stratum of over 20 feet thick. Experts pronounce it a first-class article of cannal and splint coal, very like the bituminous coal of Newcastle and the splint coal of Scotland. This coal field lies on the line of the railroad survey between Hollister and Goshen.

COMSTOCK PAPERS.—The article of this series now running in the PRESS is unavoidably postponed this week.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANKS.]

K. Agate, Amethyst, Aventurine.

Bloodstone, Brazilian pebble, carnelian, cat's eye, chrysoprase, cairngorm, false topaz, heliotrope, jasper, mocha stone, onyx, praise, rock crystal, siderite, sardonyx are all varieties of quartz. Quartz has the following chemical and physical properties:

Crystalline, form rhombohedral; colorless when pure, otherwise blue, green, brown, red, yellow, black and variegated; fracture conchoidal, brittle crystals, often enclosing impurities and foreign crystals, as chlorite, cinnabar, titanic acid, etc. When massive often carrying gold, silver, galena, zinc blende, magnetite and other minerals. Quartz is the matrix of our best mines. Specific gravity = 2.5 to 2.8. Hardness 7; scratches glass easily but is scratched by topaz. All varieties have nearly the same chemical composition and physical properties; the clear colorless crystals of quartz are often mistaken for diamonds. The fact that they are softer than topaz will serve to distinguish them from that gem. The color of the different varieties is owing to the accidental presence of the oxides of different metals.

The principal constituent of all of these varieties is silex in its insoluble state, that is, not soluble in caustic soda solution. Before the blowpipe alone, they undergo no change, but with soda dissolves with effervescence and form a transparent glass. Insoluble in acids. If previously fused with carbonate of potash and soda, they become soluble in hydrochloric acid.

Agate

Is a variegated chalcedony generally in layers, sometimes clouded. Moss agate is chalcedony with dendritic crystals of oxide of manganese and iron imbedded in it which take the form of vegetation.

The ancient "achates" was probably fortification agate. Pyrrhus, who lived 318 years before Christ, is said to have had an agate of this nature, on which was represented by the hand of nature a picture of the nine muses as perfect as a work of art. Achates was the name of an ancient town in Sicily. The moss agate was known to the ancients as dendrachtes (dendritic agate).

Amethyst

Is a purple red variety of quartz crystal, which was formerly supposed to owe its color to oxide of manganese, but specimens having been analyzed which contained no manganese, the color is now thought to be due to some peculiar compound of iron or soda. Rose quartz is a variety of amethyst only slightly tinged purple.

The amethyst was well known to the ancients, and was highly prized by them. They gave this gem the name of "aphrodisiace," or gem of Venus. By some strange supersition they believed the amethyst to be a cure for drunkenness. A good, well cut amethyst of one carat is worth from $3 to $5. A large and fine stone of good color has been sold as high as $500 The best amethysts come from Ceylon, Brazil and Siberia. Good specimens are found on the shores of Lake Superior. I have seen very good specimens in the quartz formation of the Comstock ledge and from Grass Valley.

The true amethyst must not be confounded with the violet sapphire, which is sometimes called oriental amethyst, which is much more valuable and of entirely different composition. This gem has already been described.

Bloodstone and heliotrope are names for the same variety. The color is deep green, interspersed with spots of red, like drops of blood. Good specimens command as high as $20 each. Heliotrope takes its name from having been used under water as a mirror to observe a solar eclipse.

Pliny describes the heliotrope as being "prasius," which was "horrid with spots of blood."

The carnelian is a clear bright red chalcedony. It takes its color from oxide of iron. Fine specimens come from Lake Superior. The first specimens found their way to us from Siberia, India, Arabia, Nubia and the Tyrol.

Carnelian is sometimes diversified by stripes of white, which can be cut into beautiful jewelry. It does not command a high price, but good specimens find a ready sale. The sardonyx is a variety of carnelian with stripes of white, of a thickness to admit of cutting into cameos. That is to say cutting away portions of the red, and leaving figures of red in a white base, or the reverse. A good sardonyx commands a high price. Carnelian takes its name from its flesh color.

The ancient name for carnelian was "Sard," because it was found at Sardes, an ancient town in Asia Minor, on the banks of the Pactolus. Afterwards found near Babylon.

The name sardonyx was the same anciently as now. It is the onyx in which some of the bands are carnelian, as before noticed. The first historical record of the use of this stone as a seal is the case of Scipio Africanus, from whose time it was much used, as it was found that the wax did not stick to it.

False Topaz

Is a clean yellow variety of crystallized quartz. It resembles yellow topaz when cut, but may be distinguished by its hardness, which is less than that of true topaz, and by its specific gravity. Beautiful specimens are found occasionally on the Comstock, near Gold Hill, Nevada.

Chrysoprase always occurs massive. It is of an apple or leek green color, which it takes from a portion of nickel it contains. It is translucent; luster, vitreous. It loses its color when heated. It is composed of silex, carbonate of lime, alumina, oxide of iron and nickel. A good chrysoprase suitable for a ring is worth from $25 to $30. A remarkably fine specimen has been sold as high as $60.

The chrysoprase of the ancients resembled in color the juice of the leek, a golden color, whence its name.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

CAR WHEELS AND AXLES.—Jno. W. Emerton, S. F. The invention relates to the improved car axle and wheel, the improvement consisting in a novel arrangement for providing a loose wheel at one end of the axle, which will rotate independently where a torsion, such as results when a car is moving around a curve, is applied to the axle, but which will ordinarily, when the car is running on a straight track, rotate with the axle like the fast wheel. Upon the opposite end of the axle from the fast wheel is secured a fixed disk, which is about half the diameter and half the thickness of an ordinary car wheel. In the rim of this disk is made a groove of any suitable shape, which extends entirely around the circumference of the wheel. The loose wheel, which fits on this end of the axle, is constructed with a concavity, which concavity corresponds in diameter with the diameter and thickness of the disk, so that when the wheel is slipped on the axle the disk will fit snugly in the recess. In the projecting face or rim of the socket is also made a groove corresponding with, and directly opposite the groove in the rim of the disk, and when the wheel has been properly fitted over the disk the chamber which is formed by the two grooves is run full of Babbit or other soft anti-friction metal, so that it will serve as a key to hold the two parts of the wheel together. The shaft is then secured in a vise and power applied to turn it whereby the wheel is freed so that it will rotate readily about the disks. It will be noticed that the invention does not impair the value of the wheel by cutting out its entire face and fitting the disk therein, as has been done heretofore, but the wheel is a complete one with a solid outer face which prevents sand and grit from entering between the moving faces of the socket and disk, thereby obviating a great difficulty heretofore experienced. A cap ring can cover the joint if thought necessary. The strength of the wheel is retained by preserving its center, so that viewed from the outside the wheel has all the appearance of a fixed solid wheel.

CHOPPING MACHINE.—N. A. Olsen, S. F. This invention relates to an improved machine for chopping meats and other substances into fine pieces, and it consists of a series of radial knives, which are secured to the upper end of a stem. This stem passes down through a hole in the center of the chopping block, and is operated by a cam and tappet below the block, by which the knives are given the proper chopping action. The curved face of the cam moving against the under face of the tappet will also partially rotate the spindle and knives during each lift, so that the knives are continually shifted, and thus drop in a different spot each time, thus giving the best possible effect of chopping knives. The force of the drop can be regulated as desired by weighting the lower end of the spindle. The knives are lifted and dropped vertically, and at the same time are shifted after each stroke, thus rendering them quite effective in their action.

FARM GATE.—Richard C. Whetlock, Pacheco, Contra Costa county. The object of this invention is to provide a cheaply constructed farm gate which can be opened and closed by persons on horseback and in vehicles, without the necessity of their dismounting. A person approaching the gate has only to push a crank on the shaft, on whichever side of the gate he happens to be, and turn it from him; this causes a shaft to rotate and opens the gate. When he has passed through, a similar winding of the opposite crank rotates the shaft in an opposite direction and closes the gate.

LOCK.—J. H. Woodrum, Portland, Oregon This invention relates to an improvement in locks, and it consists in a lock operated by a knob from the inside of a door in the ordinary way, and by an adjustable spindle carrying combination rings and devices, upon the outside of said door, whereby said lock may be operated from either the inside or outside, as an ordinary bolt, or be locked from the outside by a combination locking device.

THE Stevens battery, which cost its erratic builder $1,800,000, is to be sold for $52,500.

A SERIOUS rebellion is brewing in China.

[Editorial Correspondence.]

The Centennial at Philadelphia.—No. 10.

The extreme heat of the past two weeks has rendered locomotion or even writing, especially to one long accuetomed to the cool and genial climate of San Francisco, so grievous a burden that your correspondent hae been barely able to endure the same by keeping as quiet as possible within the shady precincts of the Grange encampment, which haa been universally voted by all visitors, as one of the coolest and most quiet pieces of resort in the vicinity of Philadelphia. On Sunday last, however, the 16th instant—three days ago—the thermometer marked a most welcome change by falling from well up in the nineties to a little above eighty, under which condition I have again ventured to find my way once more to the Centennial grounds, for the purpose of jotting down a few more notes for the benefit and possible instruction of the readers of the PRESS.

The exhibition has how advanced a little over two months in its progress, and still continues the theme of universal commendation. Foreign commissioners, exhibitors and visitors all commend it, both in the manner in which it has been gotten up, and in its management as well. They bear willing witness that all has been done that it has been possible to do to expedite business, and to ensure comfort and safety within the grounds. The means of transportation to and from the same are all that could be expected, and prove adequate to the largest demands. Your correspondent, in a recent interview with each of the two French delegations of workingmen now here, was pleased to hear them express their most unqualified approbation both as regards the matter and manner of the exhibition.

The Attendance.

The number of paying visitors gradually increases, notwithstanding the extreme heat, and has already raised the average daily attendance, from the opening to July 9th, to about 26,000. This average will no doubt be largely increased by the rush which will come in as cool weather approaches, fully up to the figures which I gave in one of my early letters—some 32,000—which, however, is only about one-half the estimate made and published by the Centennial commission just before the opening. In this connection it may be interesting to note the average attendance at the various European international exhibitions, which has been set down as follows:

Year.	Place.	Number of Visitors.	Days open.	Av'ge No. per day.
1851.	London	6,039,195	141	42,831
1855.	Paris	5,162,330	200	25,811
1862.	London	8,211,103	171	36,322
1867.	Paris	10,000,000	210	47,619
1873.	Vienna	7,256,687	186	39,003

As already stated, the average at our Centennial has as yet reached only about 26,000; but it is possible that with the increased numbers who will come near the close of the exhibition the attendence may go up to the general average of European exhibitions—a little over 38,000. The time of continuance of the Centennial has been fixed at 157 exhibition days—the smallest number of any of the European exhibitions, with the single exception of that of the first one at London in 1851.

I have thought it might be more interesting to the readers of the PRESS, before completing my review of machinery hall, to turn for a while to other features of the exhibition and make at least some general reference to the exhibits contained in the other principal buildings. With that view we will now enter

The Main Building.

This is the largest structure which has ever been erected for exhibition purpose, if indeed it is not the largest ever erected for any purpose whatever. It is over a third of a mile, or 1,876 feet in length—a foot for each year of our era. Its width is 464 feet, and it covers an area 21½ acres of ground. It is constructed almost entirely of iron and glass. The facades at either end are 90 feet high, while the ornamental corner towers are 70 feet in hight. The exterior is gay with turrets, flags and trophies. Empty, it would afford standing room for 450,000 people—about one-half the entire population of California. Its sides and ends are provided with galleries about 30 feet wide, which are devoted mostly to exhibits, connected with education. Although built with the intention of being taken down at the close of the exhibition, it is nevertheless a substantial and highly ornate structure, and one which presents a fine architectural appearance. Its cost was about two millions of dollars, and the wonder is how it could have been built for so small an amount of money. Readers may become familiar with the appearance of this building from the prospective view given of it in the engraving on this page.

In arranging the exhibits a grand central aisle, some 35 feet wide extends, unobstructed, except by a few minor matters, entirely through the center of the building; this aisle is crossed at its center by another of the same width, running north and south across the width of the floor. The exhibits are arranged, by nationalities, on either side of the main aisle, as shown in the accompanying diagrams—the small and more distant nations being given the place of honor, near the main entrance.

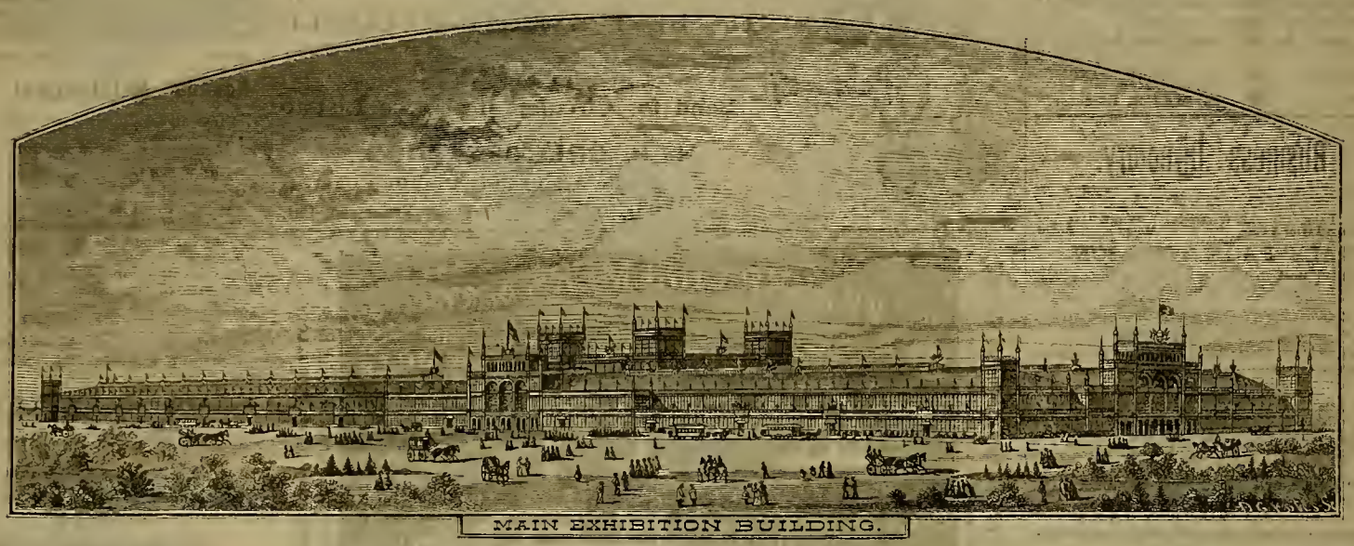
As the visitor enters this vast structure for the first time, and passes up a short distance into the main aisle, his eyes encounter one of the most magnificent sights that can well be conceived. A perfect wilderness of costly elegance, in every branch of manufacture and art, is spread out before him in a great panorame, along which his eyes wander until he is lost in wonder and amazement.

It is obviously impossible to give the reader any adequate conception of the interesting and imposing character of the exhibition in this building. At the first glance the eye is completely bewildered, as was the case with my lady friend, at the unique and dazzling exhibit which is encountered on all sides. The many beautiful articles in glass, steel, bronze, lacquer, gold, silver and plated ware, China ware, cabinet ware, elegant shawls, silks and every description of dry goods, fancy articles, etc., etc., all go to make up a grand aggregate, which has never before been seen upon this continent, although its counterpart and better, perhaps, may have been seen at Paris or Vienna; for Europe excels in this class of exhibits.

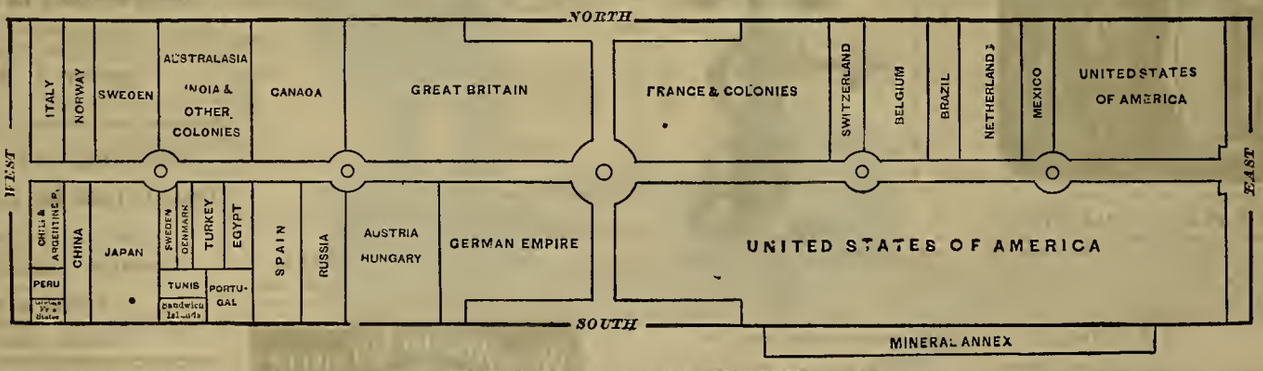
A Bird's Eye View

From the gallery at the eastern end, will perhaps give the visitor the best general idea which can be obtained of the variety, beauty and grandeur of the display in this building. From that elevated point a fine view can be obtained looking down the broad, central aisle. The whole space of nearly 22 acres of the collective industrial products of the world is spread out before the observer, almost entirely unobstructed by column, roof or gallery. Twenty-eight distinct nationalities are there represented—the United States occupying but a little over one-quarter of the space. The mass and distance is so great that it is of course impossible to particularize the various exhibits or to give anything more than a faint idea of the grand whole. Directly before the observer on either side are seen first the products of our own country. The cotton and woolen mills of the United States, and particularly the peerless exhibit of the Mission mills of San Francisco, are largely and most creditably represented. The goods are mostly shown in elegant cases, and generally in the various grades of the manufacture, from the raw material and inferior goods up to those showing the highest progress of the several exhibitors in the textile art. Of Brazil sandwiched between the two little nationalities of Belgium and the Netherlands. Passing still further in the same direction and skipping over Switzerland, we come to the great nationalties of France, Great Britain, Germany and Austria. Still further on in the distance, not observable by the eye, but known to be there by the diagram, which we still hold in our hand, may be dimly seen, most of the other foreign nationalties, all located with a most happy disregard for geographical position.

The diagram shows the relative proportion of space occupied by the respective nationalities, as well as their positions in regard to each other and in the building. With few exceptions, as shown, the space occupied by each country has a frontage on the main central aisle, and in this particular portion of its space each nation seeks to place its chief and most attractive treasures. Hence the superior views obtained along the main aisle. Some countries have enclosed the space allotted them with architectural structures of pannel work, with ornamental and emblematic archways opening into the main aisle, and lesser ones furnishing connections with the various avenues and alleys by which the space is divided up into convenient areas for displaying and examining the exhibits. Miniature marble palaces are placed at intervals along the central aisle which are devoted to the sale of that great American hot weather beverage—soda water. The central position is occupied by a raised circular platform on which, in the early days of the exposition, Gilmore's famous band was wont to discourse sweet music to the loitering crowds, which, when the band was playing, filled all the available standing room and occupied the numerous rows of seats which were placed fronting the center for quite a distance along the main aisles which diverge



MAIN EXHIBITION BUILDING.



GROUND PLAN OF MAIN BUILDING

The Exhibits in the Main Building

Are chiefly confined to the following groups:

Materials and manufactures used for food or in the arts—the results of extractive or combining processes.

Textile fabrics—wearing apparel, costumes and ornaments for the person or parlor.

Furniture, musical instruments and manufactures of general use in construction, as of dwellings, etc.

Apparatus and methods for the increase and general diffusion of knowledge. Illustrations of engineering operations and aids thereto.

Objects illustrative of the present and past

DEETKEN'S
ROASTING FURNACE,
For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 8 to 30 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adapted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

G. F. DEETKEN,
Consulting Metallurgist, Grass Valley, Cal.

Furnace can be seen on application for permit, at Grass Valley.

Marine Screw Engines

And BOILERS for driving Model Yachts from one to ten feet in length, and Row-Boats or Skiffs 16 feet and upwards in length; either plain castings, partly finished, or complete ready for use, so constructed that a speed of from six to twenty miles per hour can be easily obtained.

The Engine can be quickly detached from the Yacht or Boat, and is then suitable for Agricultural, Domestic, Mechanical, Commercial or Amateur requirements, when small power only is needed.

☞ 100 Scroll Work Designs free on receipt of Stamp.
GEO. PARR, Buffalo, N. Y.

THE O'HARRA
CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
1500 lbs of salt at 1½c	22.50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

14 & 16 Battery St.,

San Francisco.

These goods are specially adapted for the use of FARMERS, MECHANICS, MINERS, and WORKING MEN in general. They are manufactured of the Best Material, and in a Superior Manner. A trial will convince everybody of this fact.

Patented May 12, 1873.

USE NO OTHER, AND INQUIRE FOR THESE GOODS ONLY. eow-bp

MECHANICS' INSTITUTE SAN FRANCISCO

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

PREMIUM AWARDED TO W. C. WILCOX & CO. FOR BEST STEAM PUMPS. Wilcox's Patent. 1875.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

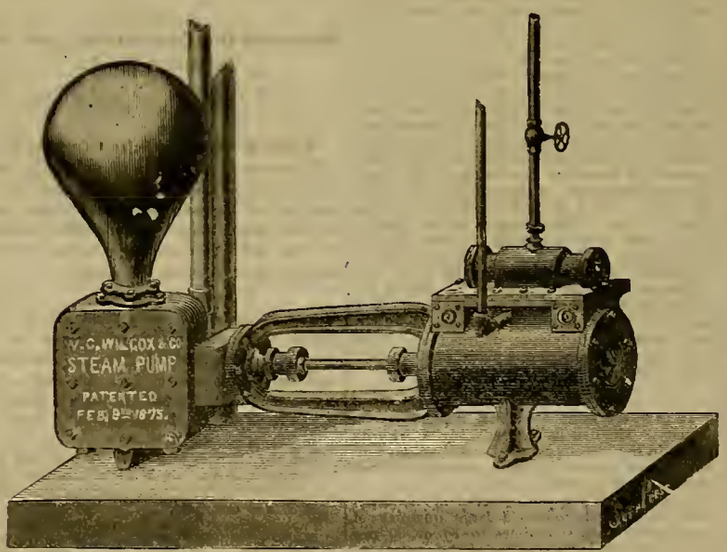
Best Established Reputation.

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition,



We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

IRON PIPE.

Having been appointed Agents for the Washington Pipe Works, we are prepared to ship from store, Pipe and Fittings at the lowest market prices.

BERRY & PLACE., San Francisco.

TREADWELL'S OLD STAND.

JOHN LUTTRELL MURPHY,

Attorney and Counsellor at Law,

NO. 535 CLAY STREET,

SAN FRANCISCO.

F. MANSELL & CO.,

SIGN PAINTERS,

423 PINE STREET,

(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors,	Gents' Furnish'g G'ds
Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotels,	Piano Fortes,

Wine Merchants, Etc., Etc.

$5 to **$20** Per Day at home. Terms free. Address G. STINSON & Co., Portland, M.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

32 Fremont Street San Francisco.

Several first premiums received for quartz mill Screens, and perforated sheet metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

ANGELL'S CHARCOAL DENTAL SOAP for Whitening and Preserving the Teeth. J. W. ANGELL, Prop., San Francisco

---

Rupture.

Any person suffering with the dangerous and distressing complaint, Rupture, and whose existence is rendered miserable, being obliged to wear the torturous metal trusses year after year without any benefit or relief whatever, can be relieved and cured without inconvenience or restriction in exercise or diet. Consultation and Examination Free. Call or address MAGNETIC ELASTIC TRUSS CO., 609 Sacramento street, (up stairs.) San Francisco.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes; Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.

TUBBS & CO.,

o2l 611 and 613 Front street, San Francisco

(Continued from Page 94.)

Idaho.

THE POORMAN.—Idaho *Avalanche*, July 29: Work is being steadily prosecuted in this mine and with the most promising results. The force of men employed is not very large, but they are operating to the very best advantage, the work for the past few months consisting principally of prospecting and opening up. The seventh level drift has been run in the north of the shaft about 700 feet, and has now reached a splendid quality of ore. From a point 450 feet north of the shaft, operations have resulted in showing up considerable rock, although not existing in heavy bodies. Much of it, however, has been unusually rich, and there are no doubt large veins in the immediate vicinity. A winze has been sunk a distance of 475 feet north of the shaft and is now down about 50 feet, from which point they are drifting northward. At nearly every point of these operations the ore has presented a very promising appearance, and also south of the shaft in the fifth level, where there have been some first-class developments. Between the fourth and fifth levels, where an air shaft has been raised, much good rock was found. The principal part of the work done recently was carried on the north side of the shaft, the object being to get beneath the old works and open up the ground so as to make a connection with the same. All these and other operations looking to the prospecting and opening up of the mine with a view to working it on a larger scale have been attended with the most promising results. The developments are unusually satisfactory.

THE REVENUE.—This mine, which in former years was one of the best paying little mines in this immediate vicinity, was recently leased by the owner, Mr. Frank Hunt, to Messrs. Duffey, Shaw and Jones, a trio of experienced miners, who have already commenced to remove the water and make preparations for an active campaign. Work will be vigorously prosecuted for the coming year, the period for which the mine has been leased.

CHESA MINES.—Work is progressing splendidly at the Potosi mine, near town. Mr. Peck has increased his force of workmen recently. A connection has been made with the old works and the quartz now being taken out is quite rich. Nearly 50 tons of ore are now on the dump. In the Belle Peck the tunnel is making good progress. A rich ore body will be approached in a few days. W. H. Dewey has purchased the Columbia mine not far from Oro Fino, and put men to work there. In former days this mine turned plenty of bullion out and it is generally supposed that plenty of good rock exists there yet. Frank Hunt's Wagontown bonanza, the Last Chance, is looming up more brilliant every day. The Leonard mill is running day and night on Wagontown rock.

Montana.

MINING ITEMS.—Butte *Miner*, July 25: The Butte placers are yielding $500 per day. Mr. Esele continues work on his claim in Silver Bow creek, and is doing well. The Dexter mill will start up again to-morrow, all breakages having been repaired. There are rumors of more mills being put up in Butte within the next three months, but we are unable to give facts at present. In the Mountain shaft at a depth of 15 feet, foul air was encountered, and Messrs. Cameron & Co. are running a day and night shift and hoisting large quantities of first-class copper ore daily. In German gulch the placer mines are working full time. The waters had commenced to fall on last week, but the recent rains have had the effect of filling the ditches again to their full capacity. The diggings are paying fair wages to those employed. The number of white men in the gulch is quite small, 15 in all, while the Chinese engaged at work count up to 92. The Purvine pan which has been under construction at the Centennial mill, for some time past, has been completed, and is now being put in place, and will shortly be in operation. The work upon the reverberatory furnace is being rapidly pushed forward, and they are fast assuming a finished appearance. The mill is working upon ore taken from the Rainbow lead, which has every indication of running to an average grade, though taken principally from croppings. Geo. D. C. Hibbs, of the Rumley mine company arrived in Butte this morning from Argenta, en route home. Mr. Hibbs interviews as follows about the Argenta country: Messrs. Kelly & Kinney are running a drain in Rattlesnake creek, commencing about three and one-fourth miles below the town. They expected to find a big placer mine when bedrock is reached, and are displaying commendable nerve in opening and developing this mine. A Bannack company have bought the Kelly placer ground above Argenta, on the old Bannack trail, and are bringing a ditch in from Rattlesnake creek to work on the same. Ore is now being hauled from the Trapper mine to Stapleton's works at Argenta, and they will start up running on full time at an early date. Argenta looks lively and wears the visage of a bustling business town.

Oregon.

GALICE MILL AND MINING COMPANY.—Ashland *Tidings*, July 27: A large amount of working stock is taken up, and with a fair show of being full in a short time. The working stock is sold at 50 cents a share, when 200 shares or upward are taken by one party. The company have bought in San Francisco a full set of assaying apparatus and all necessary accontrements for testing ores.

GROUSE CREEK MINES.—Parties returning from these mines give very favorable reports of their richness. There seems to be a little history connected with them. At the time of the great exodus to the mines in Idaho and British Columbia, there were a number of miners working on Grouse creek, who were induced to leave by the fabulous stories of these northern gold fields. The location being isolated and away from any thoroughfare, it has lain unnoticed until recently. It was discovered that some Chinamen were at work on the mouth of the creek, and apparently doing well. Coarse gold is found in good paying quantities.

MACHINERY ARRIVED.—Oregon *Sentinel*, July 26: The machinery for working the Queen of Bronze copper mine, at Althouse, Josephine county, arrived in Crescent City on the last trip of the steamer *Empire*, and will be hauled to the mine and put in working order shortly. The owners of this mine have great confidence in its richness and are determined to develop it as soon as possible.

PACK TRAIN.—A pack train left town yesterday for Beaver creek, carrying provisions, tools, etc, for the miners who are working on the China bar ledges.

A BIG PROSPECTING PARTY.—Hundreds of miners, pilgrims and others are in the Black hills, unable to obtain property or work. Efforts are being made at Deadwood City to form a prospecting party, 1,000 strong, armed and equipped for the undertaking, to go into the Big Horn and Wind river countries, and give those regions a thorough inspection. It was believed extensive and paying mines would be discovered in the sections named. It is evident that the time approaches when a strong column of adventurous men, disappointed in their expectations and ventures, will move in organized shape out of the Black hills and into the reputed, but comparatively unexplored, gold sections of Eastern Montana. The Hills, according to the best authorities, are already overrun, with not one in a score backing in the smiles of fickle fortune.

Facts about Peat.

No. 1.

[Written for the PRESS by SAMUEL PURNELL.]

Peet is a species of fossil fuel, occurring in almost every country, and is one of the most extensive sources of fuel known. Its formation is progressing at the present day. Scotland, it is said, contains a peat bog area of 1,000,000 acres, and Ireland of nearly 3,000,000. Canada contains very large areas, the amount of which is not definitely known, but it is thought that a great part of British America is covered with peat. The United States is abundantly supplied in its northern part. Massachusetts is known to contain at least 125 square miles of peat, with an average thickness of six feet. The great Dismal Swamp, of Virginia, is a peat bog. It is generally found in moist climates, in level countries, and where imperfect drainage exists.

Formation.

Peat is a product entirely of vegetable origin. In atomic composition it differs less from wood than in appearance, and in the change it has undergone chemically through the agency of time and pressure. In low places where ponds collect, and the evaporation, drainage, and percolation are not sufficient to carry off all the water, there grows around the borders of these ponds various kinds of plants, such as rushes, mosses, etc. These by reproduction increase and soon creep toward the center, till the whole surface becomes covered. In the course of time race succeeds race, the covering grows thicker, sinks down into the water, grows upon the top, and the whole pond becomes a mass of vegetable matter. These bogs often rise by gradual accumulations and overwhelm the adjacent lands, which also become a marsh, thus spreading the borders of the bog constantly. Sometimes whole forests are found at the bottoms of bogs. Their extent and depth vary with the location. The bogs of Holland are about six feet in depth; many of those in Ireland are from 30 to 40 feet in depth, and some of those in California are 30 feet deep. A peat bog dug out will renew itself every five or ten years.

Varieties of Peat.

Being the product of the decomposition of various plants during a long succession of ages up to the present, it is natural to expect that when cut vertically differences in its composition should be shown. Thus peat may be classed into recent and older. The first, bears distinct traces of its origin in the roots, stems and leaves of plants, the structure of which is still retained. Sometimes it is porous, tough and elastic, often very brittle. Recent peat glides into that of older, where no traces of a fibrous mass are observed. When cut it is fine in the grain. Old peat is often semi-gelatinous. Preference is always given to old peat, both from its superior density and the greater heat which it evolves when undergoing combustion. The color of peat, which is usually a brownish black, is no indication of its quality. In appearance it resembles pressed hay. The presence or absence of earthy matter and sand is the chief cause of the difference in the heating force of peat. These impurities are always found after combustion, in the ash, causing this residue to form from 2 to 50 per cent. of the whole. In all bogs the quality of the fuel improves, and the percentage of carbon increases with the depth. The many varieties of peat will in part account for the widely different views held in relation to this fuel. What has been found true in one place is often found to be totally inapplicable in another.

Density.

In part, the value of a fuel depends on its density. The density of peat varies with its depth in the bog, its original composition, and the mineral matters which it contains. When freshly cut it is saturated with water to the extent of 80 or 90 per cent. Ordinary air dried peat mechanically retains a large quantity of water, amounting sometimes to 30 or 50 per cent.; and this is irrespective of the water developed from the combustion of its oxygen. It always contains at least 20 per cent. of moisture, and this expends a large amount of the heat resulting from its burning carbon for its evaporation. When intended for commercial purposes it is much improved by pressure or condensation; it thus acquires strength and solidity enough to bear transportation and to burn to a firm charcoal. It may also then be burned more economically.

The want of density has been called the "characteristic fault" of peat. Its density is never as great as that of wood; consequently it is much less than coal—about one-fourth as much. There is little or no advantage in drying peat artificially, as it will re-absorb moisture from the air, and become as the ordinary air dried article. The density of air dried peat is rarely more than .3 or .4 that of water, and a cubic foot of it weighs only from 13 to 15 pounds. Peat in the bog may be estimated to weigh from 2,000 to 2,400 pounds per cubic yard; drained *in situ* from 1,300 to 1,500 pounds per cubic yard. Ordinary air dried Bavarian peat weighs 18 pounds per cubic foot. Weight for weight, dense and ordinary peat have about the same calorific value.

Composition.

The centessimal composition of the average European peat, not considering ash, is as follows:

	Carbon.	Hydrogen.	Oxygen.	Nitrogen.
Surface peat....	60.	5.8	33.16	.9
Dense peat.....	61.2	5.6	32.	1.5

A specimen of German peat, air dried, gave the following results: Carbon 60 63, hydrogen 6.04, oxygen 33 32. Supposing all the oxygen combines with the hydrogen to form water, it would contain carbon 60., hydrogen 2., and water chemically combined, 38. This specimen of peat had therefore the following composition (neglecting ash): Carbon 45., hydrogen 1.5., water chemically combined 25 5, and hygroscopic water 25.

No centessimal analysis of California peat has yet been reported, but when made it is not likely to be more favorable than the above. The amount of oxygen in a fuel largely determines its calorific value; the more oxygen the less value. For the sake of comparison between the composition of peat and the lignitic coals of this coast, the following analyses are annexed:

	Mt. Diablo.	Coos Bay.
Carbon.....	59.72	56.244
Hydrogen.....	5.078	3.379
Nitrogen.....	1.008	.42
Oxygen.....	15.69	21.315
Sulphur.....	3.916	.810
Water.....	8.94	13.285

By comparing the above with the analyses of peat, it will be seen that the amount of carbon (on which the value of a fuel mainly depends) in the two fuels is about the same, also the quantity of hydrogen. But in the amount of oxygen (a diminisher of value) the coal has much the advantage, having but about half as much. In moisture, also, the coal has the advantage, containing only from eight to 15 per cent., as against at least 20 per cent. constant moisture in air dried peat. These analyses show that of these two fuels the peat has a less calorific value or heating power, weight for weight, than the lignitic coals of about 33 per cent. It will be shown further on that compared with good bituminous coal peat is but one-half as valuable.

Good peat contains usually from five to eight per cent. of ash; and inferior may hold as much as 35 per cent. Best Irish peat contains about four and one-half per cent. of ash. A partial analysis of peat from Venice island, California, showed six and one-half per cent. of ash. Peat contains naturally no sulphur or arsenic, but its ashes are rich in phosphorus. Peat should be thoroughly air dried before being used, as a few per cents. of water will sometimes condemn that which otherwise would be of good quality. When bought by weight not only is all unnecessary water paid for, but the heating power is greatly injured; and if bought by measure the most interior kinds are the most voluminous. In California it should be purchased by weight after at least 60 days of air drying.

Mechanical Ore Concentration and Separation.—No. 2.

(Written for the PRESS by FRANCIS F. M. CAZIN, M. E., Santa Fe, New Mexico.)

Metallurgy—What this Science Consists Of.

Metallurgy is the science of profitably treating metallic ores, so as to concentrate or reduce the valuable parts contained in these ores or to transform them into marketable material. To the realm of metallurgy belong as well chemical as mechanical metallurgy.

Chemical Metallurgy

Has as its object, the changes that will result in any process applied to ores or minerals in the chemical combination of elements composing such ores or minerals. (In this distinction, dissolution, although not involving a change in the order of atoms, is considered a chemical action.) Mechanical metallurgy has as its object, the changes that will result in any process applied to ores or minerals in the local arrangement of the visible particles composing such ores or minerals.

The processes belonging to the realm of chemical metallurgy are designated as dry processes when heat is applied; as wet process when a liquid is applied.

Dry processes applied in chemical metallurgy are: Roasting, smelting, sublimation, distillation, evaporation (by heat), and crystallization.

Wet processes applied in chemical metallurgy are: Amalgamation, extraction, precipitation, cementation and solution. The four last actions are designated as "leaching."

Both dry and wet processes are called "reduction." The processes belonging to the realm of mechanical metallurgy are designated as dry processes—"concentration" and "separation."

Concentration is the increasing of the percentage of valuable particles. Separation is the dividing into valuable particles of one or of different nature, and into particles of waste material. The concentration and separation is effected by the dry process or wet process. Dry concentration is the process where air is utilized as a medium for mechanical action. Wet concentration is the process where a liquid (water) is utilized as a medium for mechanical action.

Mechanical Metallurgy, or Mineral Dressing.

Mechanical metallurgy is also called the art of mineral dressing, and as the object of mineral dressing is designated especially as the concentrating of valuable particles contained in ores to a higher percentage by separating the waste parts therefrom; also the separation of valuable particles, one kind from the other when differing in quality.

By mechanical separation (mineral dressing) only such materials (particles) can be separated as are mechanically combined, but none which exist in a chemical combination. Thus galena may be separated from quartz, fluor spar or baryta by mechanical separation, but the lead and sulphur contained in the galena can only be separated by a chemical process. Thus the nature of the combination of materials, whether mechanical or chemical, determines the line of application of one or the other metallurgy for separation. Mechanical metallurgy will never be able to separate a chemical combination, but chemical metallurgy may separate as well mechanical as chemical combinations. Therefore chemical metallurgy will be resorted to even for the separation of mechanically combined materials where either the science of mechanical separation has not been sufficiently developed to effect separation, or where it proves more expensive than the other. As long as there is a difference in specific gravity of materials mechanical separation may be applied, and as mechanical separation is the cheaper one in general, it should be applied to the outside line of its realm.

As long as two different particles of minerals differ in their specific gravity they can be separated by the art of mineral dressing. To separate mineral particles not differing in their specific gravity is an achievement which, in general, is not attained by this art, but only in some special cases. In these special cases the difference in the crystalline or amorphous shape of particles is the quality on which the work of separation is based. Thus the limits of mineral dressing are in general reached where there is no difference in specific gravity, but it may in special cases be carried further by experience and ingenuity; but before attempting in this line anything supposed to be new, mine owners should apply to some experienced and scientific mineral dresser, because what may appear to be new to the adventurer may be old to the science, and if experience has already proved it to be inadequate, an expense in a wrong direction may be saved and applied to some apparatus, well established for appropriateness and efficacy, by long experience. Ingenuity without experience is in mineral dressing a danger—a perilous contribution, resulting in all instances without hardly any exception in resultless expense, failure and ruin.

To separate the different parts constituting a mine product (ore), according to their difference in specific gravity will not in all cases be synonymous with "mineral dressing" or "concentrating." In cases where the ore contains two different kinds of valuable parts, one kind of higher specific gravity than the particle without value (gangue matter, rock), and at the same time another kind of the same specific gravity as the matter having no intrinsic value, mineral dressing would come in only with a limited applicability; and if the higher value was in the matter of a specific gravity equal to that of the particles without value, mineral dressing must be considered as inapplicable.

CASSIAR MINES.—A dispatch from Victoria says: News from Cassiar intimate that every one is confident that the district will prove as remunerative as in the preceding seasons. Rich ground has been struck on Snow creek, a tributary of McDame creek, and four men in one week, ending July 3d, took ont $6,000. Provisions are scarce and dear.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

DE HARO M. CO.—July 29th. Location: Storey county, Nev. Capital, $10 000,000. Trustees—J. W. Tripp, John Linehan, Frank Moyer, I. N. Thorn and S. D. Barstow.

YOLO M. CO.—Same location, same trustees and same capital.

GEORGE DOUGLAS M. CO.—Same location, same trustees, with the addition of L. C. White, and same capital.

MOUNT HOON M. CO.—Same location, same trustees, with the addition of John Skinker, and same capital.

VANCOUVER M. CO.—Same location, same trustees, with the addition of Frank Moyer, and same capital.

SABINE M. CO.—Same location, same trustees, with the addition of John Skinker, and same capital.

ETNA MILL & M. CO.—July 29th. Location: War Eagle ledge, Bradshaw district, Arizona. Capital stock, $3,000,000. Trustees—H. H. Allen, Henry Sweetapple, Geo. B. Gamman, Geo. B. McAneny and W. Lent.

SKIPPEL G. M. CO.—July 29th. Location: Dogtown district, Butte county, Cal. Capital stock, $3,000,000. Trustees—J. V. P. Mathis, W. F. Thomas, Newell Winants, J. L. Willits and J. B. Onstine.

SOUTH UTAH M. CO.—July 29th. Location: Storey county, Nev. Capital stock, $2,000,000. Trustees—J. J. Seville, E. D. Wright, Geo. W. Townsend, James H. Ryan and F. G. Bouton.

MELBOURNE M. CO.—July 28th. Capital stock, $10,000,000. Trustees—C. R. Jones, E. R. Warasw, S. N. Putnam, R. G. Brush and E. F. Stone.

PYRAMID LAKE M. CO.—July 28th. Capital stock, $10,000,000. Trustees—S. Coop, D. Cook, W. F. Myers, W. M. Lent and F. Oshiston.

VOLCANO G. M. CO.—July 28th. Location: Amador county, Cal. Capital stock, $10,000,000 Trustees—Geo. Mack, J. Bluxome, J. W. Farren, B. F. Smith, N. G. Young, A. Neatte and E. L. B. Brooks.

GOLD STRIPE M. CO.—July 28th. Location: California. Capital stock, $8,000,000. Trustees—R. E. Brewster, Abraham O Heisey, Edmund Green, H. C. Bidwell and Angus McIntyre.

PEOPLE'S TELEGRAPH CO.—July 28th. Object: Operating a line between Mohair station and Darwin, Cal. Capital stock, $50,000. Trustees—Patrick Reddy, Geo. H. Willard, J. G. Riley, S. E. Holcomb and H. H. Pearson.

Continued from Page 97.

efforts for the improvement of the physical, intellectual and moral condition of mankind.

Articles of vertu, taste and coriosity. Objects, statuary groups, elo., illustrative of various nationalities.

Egypt and Japan have introduced their exhibits into this building. Each nation here makes such exhibits as are best illustrative of its social relations, of the condition of the arts and sciences within its dominions, past and present. Sweden, Australia and Chile have been suffered to depart somewhat largely from the general plan, in order to bring all their exhibits more closely together at a single point. There is no machinery in the main building.

National Characteristics.

One of the chief and most interesting features connected with the main building is the effort made to illustrate there the national peculiarities of the several peoples there represented. Going through this buildlog is very much like making a tour of the world. You meet the inhabitants of the several nations in their various costumes; you behold their national characteristics truthfully and literally portrayed. This feature of the exhibition was pleasantly illustrated in the early part of the exhibition by a little incident, which may be told as follows: Three little boot-blacks, with their boxes over their shoulders, more intent on seeing the show than in the prosecution of their calling, sauntered into this building and stood for a while gazing upon the novel scene around them, when, with a happy thought, one of them fully took in the situation, and exclaimed to his two companions:

"Boys, let's take a trip to Germany"

"Yes," responded another, "and I'll make the trip pay by giving you two fellers a job."

Off they started into one of the alleys where he placed his feet on the boxes of the other two, set them to work polishing his ragged shoes, at the same time thrusting his hands into his pockets with the most nonchalant air imaginable, drew out his handful of change from which to select the pennies to pay for his "shine." A number of bystanders who had been drawn together by the off-hand notice and novelty of the occurrence, were not a little amused by the scene. W. B. E.

Exhibition Grounds, July 18th, 1876.

Aid for Boys and Girls.

The Boys' and Girls' aid society of this city is doing a good work and is worthy of all encouragement. The object of the society is to improve the condition of the homeless and neglected boys and girls of San Francisco. The society's rooms are at 68 Clementina street, S. F.

One branch of the society's work is to secure homes for the destitute, and perhaps some of our interior readers could secure from them boys and girls if they have need of them, or a warm place for charity's sake. From the second annual report of the society, we take the following outline of the work in this branch of the organization's effort:

"It is our purpose to give a home to all applicants destitute of friends, until we can find permanent homes for them, and thus far we have had to turn none away, though the scarcity of desirable places causes this branch of our work to be attended with many difficulties. Thus far we have made provision for 65.

"Our efforts have been directed of course, chiefly to children, but destitute men and women often apply to us for help. These we send out of the city if they will go, believing the country the better place for them. One young man who had traversed the city for days unable to find employment even for board, was furnished with transportation to the farming regions of San Jose valley, where he found work the same day at $20 per month. Of the others sent out in this way we have not heard, but as their faces have not since appeared to us, we trust they are safely harbored."

CARSON VALLEY.—Of the probable future of Carson valley, the Genoa *News* draws this very doleful picture: A few more years and the beautiful pine forests that surround Lake Tahoe and cover the eastern slope of the Sierras from the Truckee to Silver King, will have been laid low by the woodman's ax. The splendid mountain lake, the wooder and admiration of the world, will then look like a frog-pond in the desert, and the grand old peaks of the Sierras will lift up their bald heads to the sky, the very emblems of desolation. The snow that falls on them during the winter months will dissolve almost instantly when exposed to the hot rays of the summer sun, and pass off in a body to flood the valleys below. This done, Carson valley will be left a barren waste for the remainder of the summer and fall, and the mills along from Empire to Dayton be run by the drainage from Sutro's tunnel.

IN regard to the recent action of Congress, deciding that articles on exhibition at the Centennial exposition might be sold and removed from the grounds at any time, the Customs authorities of the exhibition gave an explanation that it is only duplicates of exhibited articles that are permitted to be taken away.

GLENN'S SULPHUR SOAP is a positive inspiration. It was a happy thought to combine the remedy, which of all others is beneficial in the majority of cutaneous diseases, with a pleasant and pure soap, by means of which it can be brought in contact with affected parts. Sold everywhere.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING JULY 25TH, 1876.

John W. Emerton, S. F., car wheels; Samuel Green, Los Angeles, Cal., compositions for manufacturing illuminating gas; George Greiner, Sacramento, Cal., violin pianos; John Q. Grinnell, Stockton, Cal., field derricks; Caspar T. Hopkins, S. F., street railroad rails; Anson Scott Levake, S. F., car wheels; Nills A. Olsen, S. F., ment choppers; John W. Platt, Mineral City, Nev., fuse lighter-; Geo. C. Price and Thos. G. Morgan, Santa Rosa, Cal., earth boring machines; Richard Whitlock, Pacheco, Cal., farm gates; John H. Woodrum, Portland, Ogn., combination locks; Samuel H. Wheeler, S. F., valve motioo for steam engines.

——The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect secrecy and in the shortest possible time.

General News Items.

BELKNAP has been acquitted.

SCATTERING cases of smallpox are reported in several places in the State.

SILVER at Amsterdam has risen from 93 to 95 gilders per kilogram.

TEXAS has now over 80,000,000 acres of public land.

THE gold excitement in Northern Georgia is at fever heat.

TWENTY-ONE wheat vessels cleared for Europe last month.

"SMUGGLER" beat "Goldsmith Maid" at the Cleveland races.

MOST REV. SAMUEL BUTCHER, Premier Bishop of Ireland, is dead.

THE enrolled militia of San Francisco this year numbers 13 814. Last year the return was 14,420.

THE Atlantic coast has been visited by a heavy and continued rainfall, which is of vast benefit to the country.

THE new Liverpool docks are completed, so that now the docks of that port cover an area of 420 acres, and are valued at $100,000,000

THE appropriation for the expenses of the Congressional committee to inquire into the Chinese immigration has been passed.

GAANT is said to have remarked the other day that he should go to England in March and visit his daughter. He thought he might travel in Europe a year or two, and then return home by way of China and California.

THE mother of Charlie Ross is stopping at Rockfield, Mass., with her five remaining children. She believes that her boy will yet be recovered, or that she will receive positive evidence of his death.

IT is reported that Garner, by his will, has left $1,000,000 for the support of an opposition ferry running to Staten Island, and that the New York club house at Stapleton is made a present to the olnb. The house cost $174,000.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

The Mechanics' Fair Daily.

This journal, printed and issued in the Pavilion of the ELEVENTH INDUSTRIAL EXHIBITION, and circulated free, will be a superior publication. It will contain all OFFICIAL INFORMATION during the Exhibition, commencing Aug. 8th, 1876 ITS ILLUSTRATIONS will furnish accurate views of NEW INVENTIONS AND MACHINERY.

The volume will give a substantial and readable RECORD OF THE FAIR, quite valuable for reference and preservation, in addition to a goodly variety of other reading matter, daily embracing GRAPHIC PARAGRAPHS AND HUMOROUS INCIDENTS, making altogether a paper eagerly sought for (both in and out of the Pavilion) by nearly a QUARTER OF A MILLION OF READERS during the term of the Exhibition—a circulation reaching a greater number of different individuals than that of any publication yet issued.

We shall make a specialty of inserting ATTRACTIVE ADVERTISEMENTS, representing the leading firms in nearly EVERY BRANCH OF TRADE AND INDUSTRY on this coast, upon favorable terms, soliciting such as we believe will be most benefited by advertising in a well conducted, enterprising and everywise meritorious journal.

This beautifully illustrated sheet, issued upon such an occasion, will receive close attention, and its contents—both reading and advertising being original—will be closely scanned throughout.

THE IMMENSE PAVILION has been improved for the coming Fair. An unusually large amount of space for exhibits has already been engaged. Special exhibitions and new and attractive features will be introduced, calculated to make the Fair of 1876 a GRAND SUCCESS.

Orders for advertising, sent in early, will receive careful attention.

The undersigned, publishers of the MINING AND SCIENTIFIC PRESS, have successfully issued a popular daily in the Mechanics' Fair during seven Industrial Exhibitions since 1864, and we are now confident of making the coming volume surpass all its predecessors in its standard of value as a reading journal of art and information and a medium of first-class business announcements.

We have been awarded by the managers of the Exhibition the EXCLUSIVE PUBLISHING AND ADVERTISING PRIVILEGES of the Eleventh Industrial Exhibition, and are determined to accomplish a work creditable to the MECHANICS' INSTITUTE, to OUR PATRONS, AND TO OURSELVES.

DEWEY & CO.,

Publishers and Patent Agents, No. 224 Sansome street, S. E. Cor. of California, S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Antilles Mining Company—Location of

principal place of business, San Francisco, Cal.

Notice is hereby given, that at a meeting of the Directors, held the seventh day of July, 1876, an assessment of 20 cents per share was levied upon the capital stock of the corporation, payable immediately, in U. S. gold coin, to the Secretary, at the office, No. 327 Sansome street (third floor), San Francisco.

Any stock upon which this assessment shall remain unpaid on August 16th, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, September 8th, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

H. M. MORGAN, Secretary.

Office, 327 Sansome street, San Francisco, Cal.

Cherokee Flat Blue Gravel Company—

Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment, No. 30, levied on the eighth day of June, 1876, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
A Caselli	17	4608	$230 40
Mrs Mary W Farrington	35	144	7 20
Mrs E M Walton, balance of certificate No. 21	128		
shares sold for assessment No. 35	81	73	3 65
George W Ramsay, balance certificate No. 36,			
320 shares sold for assessment No. 35	83	231	11 75

And in accordance with law, and an order of the Board of Directors, made on the eighth day of June, 1876, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, room 13, No. 328 Montgomery street, San Francisco, Cal., on Saturday, the fifth day of August, 1876, at the hour of two o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

C. H. BOCART, Secretary.

Office, Room 13, Safe Deposit Building, San Francisco, Cal.

Office South Comstock Gold and Silver Mining Company.

NOTICE.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of trustees and the transaction of such other business as may be presented, will be held on Monday, the 21st day of August, 1876, at two o'clock P. M., of that day, at the office of the company. Transfer books will be closed on Wednesday, August 16th, 1876, at three o'clock P. M.

J. M. BUFFINGTON, Secretary.

Office, Rooms 3 and 4, No. 311 California street, over Ætna Insurance Office, entrance 309 California street, San Francisco, Cal.

Kearsarge Consolidated Quicksilver Mining

Company. Principal place of business, San Francisco, Cal. Location of works, Lake Mining District, Lake County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the first day of July, 1876, an assessment of fifteen cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at No. 10 Stevenson Block, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 28th day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 16th day of September, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES McHAFFEE, Secretary.

Office, Room 10, Stevenson Block, San Francisco, Cal.

Mariposa Land and Mining Company

of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the sixth day of July, 1876, an assessment (No. 6) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 9 Nassau street, New York.

Any stock upon which this assessment shall remain unpaid on the seventh day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the second day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Office of the Tintic Milling and Mining

Company, San Francisco, Cal., July 14th, 1876. The annual meeting of the stockholders of the Tintic Milling and Mining Company will be held at the office of the company, No. 310 Sansome street, San Francisco, on Monday, August 14th, 1876, at two o'clock P. M., for the election of directors for the ensuing year, and the transaction of such other business as may be brought before the stockholders. By direction of the Board of Directors. H. CLAY MILLER, Secretary.

San Francisco, July 14th, 1876.

Umpire Tunnel and Mining Company—

Location of principal place of business, San Francisco, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No 6), levied on the 23d day of June, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

The ALLEN ENGINE GOVERNOR.

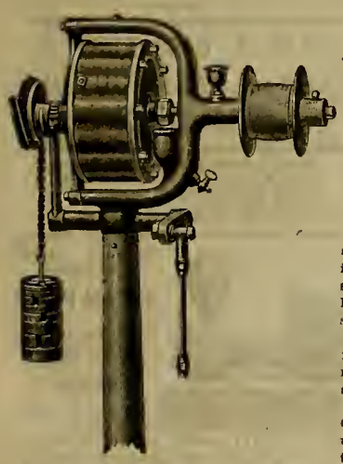

Fig. 1. For Variable Cut-Off Engine.

Uniform Speed in the Working of Steam Engines.

THE SIMPLEST AND MOST EFFICIENT GOVERNOR YET CONSTRUCTED.

ECONOMY and SAFETY.

Especially Valuable with Adjustable Cut-Offs. Capacity of Machinery Increased by Accurate Regulation of Speed.

Direct Saving of Fuel—Great Increase in Power of Engines.

The high rate of speed used acts advantageously in making the Allen Governor very sensitive; and all parts being lubricated, it works with the smallest amount of friction.

The speed of the Engine is maintained equally, without reference to the variations in amount of work being done.

The peculiar action of the Governor, which allows the use of a valve of large area, thereby admitting to the Engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced astonishing results by being attached to old engines, greatly increasing their power or effecting a direct saving of fuel, and in hundreds of instances doing both. In running an engine with the Allen Governor with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Allen's Patent Governor Valve is constructed with a double disc in a tubular frame, and is perfectly balanced, there being no spindle as in the ordinary throttle valve to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, insuring the greatest possible durability.

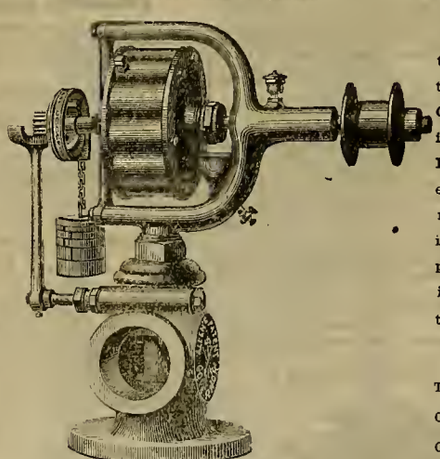

Fig. 2. Allen Governor and Valve.

We have Numerous testimonials from parties who have used this Governor, and watched its workings critically. In all cases the Governor has made the various engines to which it has been applied produce the most profitable results ever obtained.

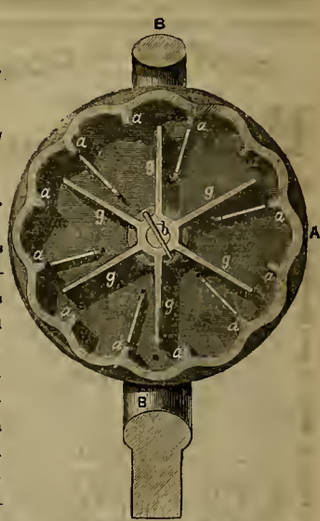

Fig. 3. Section of Allen Governor.

PARTIES INTERESTED IN STEAM MACHINERY SHOULD EXAMINE THE ALLEN GOVERNOR, WHICH IS NOW INTRODUCED ON THIS COAST FOR THE FIRST TIME. FULL INFORMATION CONCERNING IT CAN BE OBTAINED FROM ILLUSTRATED DESCRIPTIVE CIRCULARS WHICH WILL BE SENT ON APPLICATION. Address,

Mining and Scientific Press,

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid hy ns for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correepondence, and for printing a large-sized, handsome sheet, is uneqnalled hy that of any other American weekly west of the Missiselppi.

As a PRACTICAL MINING JOURNAL it has no rival on this Oontinent.

It is the only MECHANICAL, and the only SCIENTIFIC Journal of the Pacific States.

Miners, Assayers, Millman, and Metellurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Mannfacturers, Professional Men, and Progreseive and Industrial Students ehonld patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughont the world ehould profit hy its illustrations a d descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkere throughout the land, in high or humble situation, who would avoid literary trash for gennine information. ehould SUBSCRIBE AT ONOE.

11th Industrial Exhibition,

Under the Auspices of the

MECHANICS' INSTITUTE.

The managers have the honor to announce that the forthcoming Exhibition will be opened to the public on

Tuesday, August 8th,

At 11 A. M., with the nsual ceremonies. By the desire and co-operation of the leading citizens of San Francisco, the Exhibition will hs held on a much grander scale than heretofore.

The Exhibition Building, Occupying an Area of over 214,000 Feet

Of floor room, will be completely filled with the varied produ ts of the skill and industry of the people and of the soil. **Over 700,000 persons** were admitted during the last Fair. The managers intend to engage the services of the best instrumental talent of the country, so as to enable them to give unequaled

Musical Concerts Afternoon and Evening.

In every department applications for space far exceed expectations, and surpass those of former Fairs. Intending exhibitors must not delay filing their applications, otherwise they will he excluded.

The Exhibition will continne at least one month.

There will he no charge for exhibiting space.

Application for space or for information ehonld he addressed to the Secretary of the Board of Managers, Eleventh Exhibition, 27 Post St., San Francisco, or to J. H. Gilmore, Supt., at same address.

A. S. HALLIDIE, Pres't,
J. H. CULVER, Sec'y.

SAN FRANCISCO, SATURDAY, AUGUST 12, 1876.

VOLUME XXXIII Number 7.

Academy of Sciences.

The regnlar semi-mnthly meeting nf the California Academy of Sciences was held on Monday evening last; Dr. Stont in the chair.

The donations to the cabinet were numerons. C. D. Gibbes donated samples of coal from Anstralia, Vnncouver's Island and Monnt Diablo; of rock salt from Cheshire, and of lignite from Cook's inlet, Alaska. Mr. Goodwin, several mineralogical cnriosities. Mr. H. Edwards, crystals of cinnabar from the interior of a quicksilver furnace chimney, and silver ore from Anstin, Nevada; also, some plants from western Mexico. Mr. John Middleton, cinnabar from Sulphur banks, Lake connty. Governor Holden, silver ore from Elko, Nevada. Mr. Glass, calc spar and asbestos from San Antonio creek, Calaveras; and from Capt. Turner, W. G. Harford, C. H. Johnson, J. P. Dameron, W. J. Fischer, W. A. Mestayer and Dr. Stout, specimens in natnral history.

W. N. Lockington read a short paper describing some California fishes.

A Flying Machine.

Mr. C. W. Krneger, read hy permission, a paper on "Flying Machines." Mr. Krueger is not n member of the Academy, but was introdnced as the inventor of a new flying machine, which is now heing made and will shortly be tried in this city. He has been for some eight years experimenting on this subject, and now believes thut he has designed a flying machine which solves the problem nf aerial navigatinn. He read an extended snd qnite interesting paper on flying machines and their history, illnstrating his remarks hy engravings of the machines which had been "tried and found wanting." Mr. Krueger is a civil engineer by profession, snd designs exhibiting the working model of his invention at the Mechanics' fair before its close, if finished in time. His argnments in favor nf the principle of constrnction which he has adopted for the machine were quite plausible, and it only remains for the practical trial to prove the correctness of the theories.

Mr. Krueger exhibited a pasteboard model of his air ship. The buoyancy comes not from a balloon, hut from extended aero-plain surface, and great propnlsive power obtained from wings rapidly revolved and propellers astern, and for guidance he relies on the propellers, which can be operated with either a reverse or forward movement, and also a rudder and tail-piece. Steam will in part be used as a motor. The wings are arranged ou a shaft which revolves in a direction parallel to the length of the machine, and there is one of these shafts on each side of the car. There are four wings on each of these shafts, and at each revolntion, the wing, which comes in towards the car, is folded np alongside the shaft, nnfolding again at the time when it is most effective. The car will he about 60 feet in length and weigh sbont 400 ponnds. It is expected to reach a speed of from 100 to 150 miles per hour. We will give a more detailed description of this machine on its completion.

A Merited Honor.—Mr. Henry G. Hanks the first president of the San Francisco microscopical society, has been unanimously elected an honorsry member of the society. He has been an active resident member since the society started, and was, in fact, one of the first promoters of the movement to organize. Mr. Hanks has made a specialty of micro-mineralogy and has a large and constantly increasing collection of mineral slides, in sddition to his fine private collection of ores. He has for some time been engaged in arranging and identifying the mineral collections of the University of California, which embrace that of the geological survey, the Voy, the Pioche and that collected by Mr. Hanks himself. This work has now been discontinned owing tn the lack of fnnds at the command of the University, so that Mr. Hanks now gives his whole attention to his assaying business.

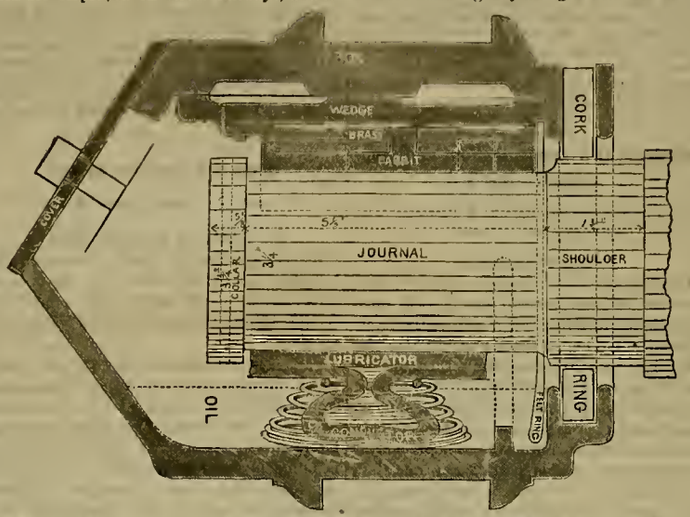
Arrangements have been made wherehy fifty tons of ore will be shipped every month from the antimony mines, situated sixty-five miles south of Winnemucca.

Notices of Recent Patents.

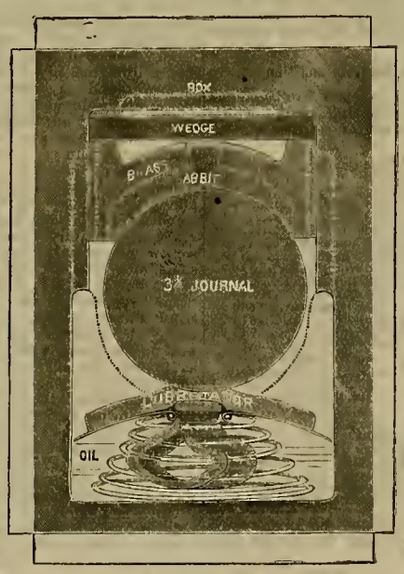
Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Rubber Rail.—Caspar T. Hopkins, S. F. This is an improvement on that class of rails which are employed on street railways, and it consists in constrncting the rails with corrngations or indentations npon their onter edges, so that it will he easy for any vehicle to cross them at acnte angles, without the difficnlty of sliding along the edge of the rail as has heretofore heen the case. The inner edge of the rail may also be provided with notches, bnt in order to assist vehicles to leave the line of tracks where the wheels fit perfectly, it will be necessary to constrnct the track so as to stop the wheel without corrngating the inner edge, as this would interrnpt the smnoth movement of the car wheel. The inventor therefore constrncts the depressed portion of the rail which receives the flange, with its inner edge rising slightly, and the depressions or corrngations are made on this edge. The effect of this construction will be to cause the back portion of a wheel to run or bind upon the edge, as soon as it is turned to leave the track, snd when it falls into the first of the depressions it will be prevented from sliding any further until its forward part has mounted the inside of the outer part of the rail so as to leave the track. This corrugation of the rails will present such obstructions that vehicle wheels will easily cross or leave the rails, and thn strain upnn the rails and road bed caused hy the side pressure of heavy teams which are attempting to cross it at an acnte ang'e with the line, will be avoided. Rails of this construction may be more or less modified in the form of the corrngations, hnt it is the intention of the inventor to form them, so that they can be as readily rolled, as those of the ordinary form, and can therefnre be furnished to the consumer at no greater cost per yard for manufactnre than the common rail.

Field Derricks.—Johu Q. Grinnell, Stockton. The improvements patented are applicable more particularly to such derricks as are used for handling hay and grain in the harvest field. The improvements consists in the employment of a novel hoop for attaching the hoom to the derrick and detaching therefrom when desired, and also in the arrangement for connecting or hinging the boom to said hoop in order to obtain an independent motion of the boom; also in the method of attaching the hoisting pulleys and elevating rope. By these arrangements the inventor provides a very ample and convenient arrangement of the derrick, whereby he adapts it for elevating hay and grain in the field. By combining the loose hoop and the arrangement for elevating it with the hinged hoom, he can nse a much shorter boom than is ordinarily used, and therefore can handle it with much greater ease. As the stack increases in hight the hoop is elevated accordingly, so as to keep the hoom in the proper relative position, to ensure speed and convenience in lifting and depositing the grain on the stack. It also enables one to build a stack as much higher than the maat, as the hoom will project above it when the hoop is elevated to the higheat point.



SIDE SECTIONAL VIEW OF LUBRICATOR AND DUST EXCLUDER.



END VIEW OF LUBRICATOR.

Improved Railroad Axle Lubricator.

We illustrate on this page an improved device for lubricating railroad axles by capillary attraction. The arrangement was patented through the Mining and Scientific Press Patent Agency, by James M. McDonald of this city. It is an improvement in that class of lubricators in which the oil is raised hy capillary attraction through a wick, and supplied to a pan which is pressed against the journal by a spring. This is considered the most economical plan of lubricating, as it takes up just as much oil as is wanted and no more.

There have always been difficulties in the applications of this kind of lubricator, which Mr. McDonald proposes to overcome. Hitherto the lubricating pad was made concave to fit the journal, hnt in that way it forms a receptacle for dnst, metallic corrosions, etc., which cnt ont the journal in time and cause considerable friction continually. In the improvement illnstrated only one part of the pad touches the jonrnal, and the dnst, etc., runs off, giving it no chance to lodge. The spring is also better adapted to the purpose.

The whole lubricator is cheap and simple, and the engravings show pluinly the details of constrnction. A cork ring is placed just around the shonlder of the journal to prevent leakage through the back end of the box. A felt ring passes around inside of the cork ring, which not only prevents the oil getting to the cork hut lubricates the rear end of the journal. Dust is effectually excinded by this device. It is now in nse qnite extensively; it has been adopted by Woodward's, Ossebolt's, the Omnibns, snd the Cluy street hill railroad companies. The manufactnrer is Wm. J. L. Monlton, 435 7th street, in this city. It is claimed that 50 per cent. is saved by adopting this cheap remedy for hot boxes and journals.

Nevada Mines.—"Fax" sends us some items from Nevada as follows: At Egan canyon Gen. Rosecrans is still drriving his tunnel, 50 inches of water coming ont, but as yet no ore. In Cherry creek there is nothing doing. The Star mine has a half million bonanza in sight, hnt don't move. In Hnnter district the Vnlcan mine looks beantifully. It is being slowly bnt surely developed. In White Pine, the Eberhardt and Aurora 30-stamp mill is running to full capscity, and from the appearsnce of the mine will do so for a long time, if silver is not knocked ont of the market. Ward district is a No. 1 camp, and has paid from the heginning, and will for years. They have worked silently and economically, and have proved an immense mine. They are now going to hnild up a snbstantial town. At Egan canyon the San Jose mill was shnt down after having put throngh 864 tons of ore. Mr. Dahlgren worked it np to 72½ per cent. with a loss of 229 pounds of quicksilver, or about one-quarter ponnd per ton. This was the same class of ore as they had lost so much quicksilver on in previons runs. The cost was $9.81 per ton, including $1 for repairs and 50 cents per ton for snpplies and improvements. This was the most snccessful run the compsny ever had. It is said that before this they had only succeeded in working the ore from 33 to 35 per cent.

Important Suit Regarding Tailings.—An important eqnity suit has been commenced in the tenth district conrt, Sutter county. The suit is brought hy James H. Keyes, who claims to he owner of over 1,060 acres on Bear river, Sutter connty, against the Little York gold and water company, (limited) and 18 other mining, water and ditch companies and individuals in Placer and Nevada counties, on Bear river and its tribntaries, to perpetually restrain them from suffering their debris or tailings from flowing into the said river or its tributaries, also from polluting or fouling the waters of the said river or its tributaries. The plaintiff claims that the deposits caused by the tailings and debris of the mining claims in question materially injnre the value of his land and improvements, and nnless stopped will totally destroy them. Damages are laid at $10,000. The snit will come on for hearing in the November term of the district court, Yuba City, on the second Monday in November.

An Ottawa dispatch says the British frigate *Amethyst* will be at San Francisco in waiting to convey Earl and Countess Dufferin and party to British Colnmbia.

A Berlin dispatch says it seems certain that the project to solve the Eastern question hy a conference of the powers has been abandoned.

CORRESPONDENCE.

Alpine County—Its Mines and Resources, Past, Present and Future.

[Written for the PRESS by VICTOR HARLAND.—No. 4.]

Silver Mountain Dislrict, Continued.

Adjoining the Exchequer mine on ths south, and npon the same lode is situated ths property of tbe Lady Franklin G. & S. M. Co. This miue consists of 2,000 feet along the lode, and is ons of ths first locations made within the district.

The amonnt of labor p-rformed thus far upon the

Lady Franklin Property

Is hut nominal, oonsistiug of a shaft situated on the mountain side, and it tersecting the lode at the slight depth of 40 feet, a sho.t surface tnnnel has also been driven to penetrate the lode at a point nearly the same dep'h from the surface, with a drift therefrom, and following the lode southerly for a distance of about 100 feet. The character of the ore here fonnd is ideutical with that extracted from the Exchequer, its adjoining neighbor. The lode where penetrated shows a width of nearly, or quite ten feet, with smooth, true walls, a general course northerly and southerly and a uniform easterly dip of ahout 40 degs. At all points where penetrated, the lode shows a quality of ore that merits more attention at the hands of the company than it has heretofore received. Assays of ore extracted have ranged from $20 to $400 per ton, and considering the shallow position beneath the surface from which this ore was taken, the extent of the property, and other evidences of its wealth which are inevitable in their conclusions, this mine in a comparatively short period would prove self supporting under efficient management. The lode is firm, well estahlished, and well defined, and explorations in the Exchequer near the dividing liue have demonstrated the fact that the Lady Franklin, while showing well upon and near the surface, has many evidences of a larger and richer deposit at a depth of 500 or 600 feet, than can he seen in the shaft or tunnel as explored. A fine location for a permanent shaft and hoisting works can he easily ohtained within the surface boundaries of the mine, and a full supply of forest timber is also within their reach in like position. In the merry days of the past, when in mountain, valley and canyon could he seen the prospector and minor, armed aud equipped for the exciting search for the precious metals, the Lady Franklin was looked upon as the pride of the district and the key to the great store house of mineral wealth—Scandinavian canyon. A company was organized, incorporated, stock issued and work of development inaugurated. Samples nf the ore extracted were taken aoross the mountains and exhibited in various localities, their heauty and richness everywhere eliciting the favor they really merited. Visitations from prominent mining men of that period were of frequent occurrence, who were outapoken with their praise of the mine and its prospects. This feeling of security and personal consciousness of prospective wealth in the near future was doomed, however, to a

Long and Lingering Struggle

Not foreseen at that early date. For some unaccountable reason, partially bassd upon erroneous reports regarding the extent of the vein and the possihle refractory nature of the ore, work was suspended and a feeling of distrust became manifest among a portion of the stockholders residing at a distance from the mine. Efforts have heen made from time to time hy parties interested and who were acquainted with the prospective wealth of the mine, to resume work and develop it to a depth of 500 feet below the present workings, but as often were theee efforts baffled hy other parties holding equal interests; consequently from the time of suspension till the present, no lahor of note has been performed.

Whatever may have been the feeling of distrust pervading the minds of the stockholders on the "western slope," regarding the value of the mine, the dissatisfied sentiment has never ruled in any manner the opinions or actions of those interested whose knowledge of the mine and its value was gained hy practical experience and daily acquaintance during their period nf labor here. Through the efforts of the present superintendent, Wm. Mercer, Esq., who is one of the original locators, a permanent title to the property has been secured hy U. S. patent; this heing the first patent issued to a mine situated in the county.

The office of the company is in San Fransisco, and a re-organization has lately taken place for the purpose of systematio development; the capital stock having heen increased to 100,000 shares. A sufficient amount of stock will he offered for sale, and intended as a working capital, encouraging advances of support having heen made by capitalists who see in this undertaking a rare opportunity for jndicious investment.

The Present Company

Is composed of men who understand perfectly the condition and appearance of the mine, its past history and experiences, difficnlties and dslays. Their re organization which took place on ths 29th ult., is ths signal for a resumption of work upon their property after a monotonous and ill-advised rest of many years, and the owners thereof need havs no fear of a failure as regarding the ultimate value of ths mins. I do not hesitate in the assertion that had the company pursued a systematic course of developmsnt even during the two years since their application was first pending, and explored their mine to a dspth of 500 feet or more, their only rsgret would have heen that the development was not inaugurated earlier. The diminutive shaft below mentioned, together with the surface tunnsl of like proportions, is the only attention, aside from the patent, this truly valuable property has ever receivsd, but it is hoped, now that this new organization has taken place within our State, the directors of this company will evince that spirit of enterprise and interest toward a permanent development of the mine that it so justly merits, and not allow it to remain, as heretofore, the victim of delay, and seemingly abandoned to all interests and purposes.

Had the mine no existing merit the apathy and inattention of the former company could he easily explained; but knowing as they did, its actual value, as shown within their own houndaries, together with the character and quality of the ore daily extracted from the Exchequer, no disinterested person other than that mythical personage—a Philadelphia lawyer—could imagine the reason thereof. The mine is situated directly within the principal mineral helt extending through the county, and although hut poorly and insufficiently prospected thus far, it still maintains the former creditable position held in the earlier days, and will prove itself worthy, if prosecuted and developed with the vigor and system generally shown hy our own local State organizations, of far more support from its adherents than it has ever received in the past.

[Copyrighted.]

Mechanical Ore Concentration and Separation.—No. 3.

(Written for the PRESS by FRANCIS F. M. CAZIN, M. E., Sante Fe, New Mexico.)

Specific Gravity.

The annexed table of minerals, arranged according to their specifio gravity, will show the cases where valuable minerals in their narticlea are not of higher specific gravity than the rock which usually accompanies them in the ore. These cases are seldom and exceptionable.

If, nevertheless, such minerals under application of the proper apparatus give results not in accordance witb general results, this probahly is occasioned by valuable parts being in a state of corrosion from atmospheric influences, and hy the change or deterioratiou of their specific gravity hy atmospheric influences. Snrface ores are likely to disappoint the application of the general rules of mineral dressing to some extent.

Ores may he classsd as, firat, ores of favor able dressing qualities; second, ores of refractory dressing qualities.

To the first class all ores helong which contain no valuable parts, unless they surpass in specific gravity by one unit all other mineral matter in the ore.

Specific Gravity of Minerals and Gangue.

As instances of the first class can he enumerated those in the following table, which shows the specific gravity of each as well as that of the gangue:

Gold (Native)	12.7 and	Quartz	2.7
Silver (Native)	10.5 and	"	2.7
Copper (Native)	8·6 and	"	2.7
Copper (Native)	8.6 and	Granite	2.5 to 3.0
Galena	7.4 to 7.6 and	Baryta	4.2
"	7.5 and	Pyrites	4.2
"	7.5 and	Zinchlende	4.2
"	7.5 and	Fluor Spar	3.1
"	7.5 and	Hornblende	3 to 3.4
"	7.5 and	Dolomite	2.8
"	7.5 and	Quartz	2.7
"	7.5	Calcareous Spar	2.6 to 2.7
"	7.6	Limestone	2.6 to 2.8
"	7.5	Sandstone	2 to 2.6
Cinnabar	6.2 to 10.2	and any of the above quoted rocks.	
Rnby Silver Ores	5.4 to 5.8	and any of above quoted rocks except Baryta. these rocks having a ap grav of	2 to 3.4
Variegated Color Copper Ore	6.0	from rocks of	2 to 3.4
Pyrites of Iron	4.5 to 4.9	from Quartz	2.7
Pyrites of Iron	4.5 to 4.9	from Granite	2.6 to 3
Copper Pyrites	4.2	from Granite	2. 6 to 3
Zinchlende	4 to 4.2	from Calcareous Spar.	2.8
"	4 to 4.2	from Flnor Spar	3.1

Aa inatances of the aecond class (of refractory dressing qualities) can be quoted, ores containing

Variegated color copper orea	5	and baryta	4.2
Fahlerz	4 8 to 5.1	and baryta	4.2
Chlorides of silver	4.7 to 5.6	and baryta	4.2
Iron and copper pyrites	4.2 to 4.9	and baryta	4.2
Zinchlende	4 to 4.2	and baryta	4.2
Malachite	3.6 to 4	and baryta	4.2
Malachite	3.6 to 4	and fluorspar	3.1
Malachite	3.6 to 4	and tourmaline	3to3.2

All ores quoted, as of the first class (of favorable dressing qualities), have been successfully and practically treated, hy the author of this treatise, with the machinery hereafter described.

In order to ascertain whether ores carrying either gold or silver, in connection with base metals and rock, helong to the first olass or not,

A Test by Assay

Will, in all cases, bs the safest. This test should he carried out as followa: Ont of an averags sample of ths ore such particles of rock should he selected as, under a good lens, do not show any particles of metallic matter. What silver or gold such rock will prove to contain by assay, inviaible even under a good lense, cannot he recovsred by dressiug. Thus, ors consisting of argentiferous galena and rock may not carry all the silver with the galena, but partly in such intimats connection with the rock that none of the specific silver combinations can be distinguished under a good lens, and this part of the silver will be inseparahle from the rock by any mechanical cnntrivanca. The test should be completed hy the assay of hard pieces of each mineral consstituting the ore. The same assay as these hard pieces will show approximately will he the assay of properly concentrated material from the ore.

Surface Ores

Having lost hy corrosion, their metallic character (luster, crystallization, cleavage,) do not, therefore, always belong to the second class (of refractory dressing qualities) bnt nnexceptionahly require a more careful treatment on acoount of the corroded metallic matter passing under any and all appliances for breaking the ore at once into the state of fine powder (slimes). In order to concentrate this powder, special and more complicated apparatus are required than for coarser sizes, into which round and natural ores will break.

Ores heing a mixture of only a small percentage of rock, but mainly of pyrites of iron and copper, zinchleude and galena, all of which minerals contain gold or silver ahout evenly divided in value, may be separated by mineral dreasing, but not concentrated, no accumulation of value in any of the separated parts heing the result of separation. Such ores are considered as belonging to the second class and as refractory.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANKS.]

K. Agate, Amethyst, Aventurine.

Bloodstone Brazilian pebble, carnelian, cat's eye, chrysoprase, cairngorm, false topaz, heliotrope. jaspar, mocha stone, onyx, praise, rock crystal, siderite, sardonyx, are all varieties of quartz.

Cat'e eye is a translucent vsriety of qnartz, which, when cut, presents a peculiar appearance, supposed to reasmble the eye of a cat, whence its name. This peculiarity is owing to its being intersected hy filaments of asbestos. Cat's eyo is fonud in small fragmeuts in Ceylon, never in pieces larger than a hazelnut. Common varieties are sold for $20 or thereahout, while the best specimens command $100. "Beli oculus" was the ancient name for cat's eye.

Chalcedouy generally takes a mammillary or botryoidal form, often forming a smooth lining of cavities. It is formed hy a gradual deposit from water holding silica in solution. It takes its color accidentally from the substances it is thrown in contact with. The most beautiful color is a delicate pink, which is quite common at Aurora, Esmeralda county, Nevada. Chalcedony is named from Chalcedon, an ancient city in Bythynia, in Asia Minor. This mineral is also found in many beautiful forms at Volcano, Amador county; in Monterey county, near Panoches; on Walker river, Nevada; between Williamson pass and Johnson's river, Los Angeles county. And in many locslities in other parts of the world.

Jaaper is always opaque and of a dull color, taking many colors. It is sometimes striped or clouded. It has a low value, bu: some varieties are very beautiful when cnt and polished. It sometimes occurs in enormous masses; luster sometimes resinous like wax. It scratches glass, but is scratched hy a quartz crystal Some very fine varieties of jasper occur near San Francisco. Jasper is always a metamorphic rock. It is generally the result of the action of heat on sandstone, which has been so changed as to lose the character of sand and become somewhat homogeneous. There ia a specimen in the collection at the Universlty from Knight's Ferry, ahowing the sandstone, one side of which has been changed to jasper. A fine variety of jasper is found near Murphy's Camp. It is of a brown color and beautifully variegated. Jasper under the name of "iaspis" was a favorite stone with the ancients.

Onyx is a variety of agate in which stripes of white and hlack alternate. This stone is used in cutting cameos, the white portion heing cut away so as to leave white figures on a hlack ground.

Siderite is indigo blue. It comes from Salzhurg.

Aventurine is quartz, massive, of a pearly or redish color, and containing thin plates or scales of mica, which give it a peculiar glimmering appearance, which is much admired in cut specimens. It is found in India, Bohemia, on the shores of the White sea, and elsewhere. The hest specimens come from Cape de Gate, in Spain. The artificial aventnriue is far more beautiful than the natural. I find a formula for making it, as foNows: Heat together for a long time, eight parts of ground glass, one part of protoxide of copper and two of oxide of iron, and allow the mixturs to cool slowly. Bnt an artificial productiou, said to come from Japan, is extremly puzzling. In cutting a thin section and examining it under the microscope, the spangles are seen tn be perfect tubnlar crystals. Mrs. Captain Nathan, of this city, has a magnificent specimen of this singular production.

The finest specimens of natural aventurine known, are two largs vases cut from this rare mineral, which were presnnted by the Emperor of Russia to Sir Robert Murchison. They are now in ths Museum of Economic Geology, of London.

The colorless variety of quartz is callsd rock crystal, or Brazilian pehhle; it is very valuable for making glasssa for spectacles, being harder and more durable than glass. A good deposit of this mineral wonld be very valuable. The Japanese excel in cutting quartz or crystal. Most magnificent spheres may he seen in the Japanese stnres cut from rock crystal.

There is a locality near Placerville where this valuable mineral is found, and which should be examined with a view to snpply the market. Good, olear pieces would fiud a ready sale in London or Paris.

Smoky quartz is known in commerce as cairngorm, from a celebrated locality in the Cairngorm mountains, in Scotland. It is common in California. The hest I have seen came from near Placerville.

Mocha-stone is quartz in which is imhedded irregular particles of the oxides of iron and manganese, different from the moss agate before described. It is found in Arabia, and is supposed to take its name from Mocha. Some very peonliar and beautiful specimens have lately heen brought to San Francisco from the Aleutian islands.

Quartz is too soft to rank high as a gem, but some of the varieties are held in high estesm. It is not generally known that a fine amethyst soon becomes dull and almoat lusterless if not often cleaned with soap and water. It is a good rule to wash such a stone frequently, with a small brush, and then to wips it dry with a towel. The more nohle gems do not require so much attention, hut even they may sometimes be so improved.

Centennial Chat.

[Written for the PRESS by MARY MOUNTAIN.]

Ever since I was old enough to understand the word "mummy," I have wished to see the real thing, and whoever enters the main bnilding at the upper end (nearest the gates of main entrance), and goes along the end corridor, will come directly upon the Peruvian department and a large assortment of

Genuine Peruvian Mummies,

Sitting upright in their glasa caaes. To us Americans they ought to he as interesting as the Egyptian article; and judging from the crowds that always surround them, we must conclude that all snch preserved samples nf humanity have a queer sort of fascination for us, mixed up with a feeling of repulsion.

If the pre-historic Peruvians were liable to gray hairs, these dried ones had not lived long enough; for their mnted looks are all of a dull black and give a more ghastly look to the shrunken faces. All the bodies are pitifully small, and confirm ono's notion of a race of pigmies; but here are spread out also the works of their hands; quaint old pottery, fabrics and weapons of war, all indicating a race of average strength and hra'n power.

Some of the heads are well developed and must have carried a fair sized hrain, and in the withered haod of one woman a distaff is held, all ready to start another yarn in case that doctrine ever comes true about the resurrection and quickening into life of the same old hodies. I have heard it said that those races who took so much pains to pressrve their bodies were

Earnest Believers in Resurrection;

But if they conld see themselves now an wretchedly atiff and withered, very likely they would he glad to drop the old creed along with the cast-off hodies and take a fresh start.

From Peru we step over to our near neighbor,

The Sandwich Islands,

And find a pleasant welcome among the beautiful things arranged for our reception.

A lovely, framed wreath of shells and mnssea surround the motto "Aloha America," meaning "Hallo," "Hurra," or any genial sentiment you like hest. The Hawaiian Superintendent of Public Instruction is present to interpret mottoes or explain for visitors any other interesting puzzle. The tasteful arrangement of ferns, mosses, grasses and delicate spatter work gives a cheerful, homey-look to this department; or is it the leather, looking so much like the product of our Santa Cruz tanneries, that made this acene to me such a familiar nook? Surely the leather looks no hetter than our own home made, hnt it has had the enterprise to come over to the great world's fair and so become "distingnished from the common hide." Here are well made saddles tor the islands aud native hoats for the ocean

(Continued on Page 111.)

MECHANICAL PROGRESS.

Bolts and Screws.

C. Fairbairn in the *Foreman*, an English publication, gives some interesting information concerning the manufacture of bolts and screws: Until very recently the whole of the bolts used were made by hand; and at the present time a large proportion of the better class of bolts, such as are used for machinery, are still made in this way. A preference seems to exist among engineers for these bolts, on the principle, I suppose, of being better known and proved. Forging bolts by hand is very similar to ordinary blacksmith's work, except that, there being always the same thing to make, special tools are used. A tool called an oliver is employed, which is simply a hammer, weighing about 30 lbs., mounted on a spindle, on which there is a lever connected with a treadle operated by the foot; this leaves the workman's hands at liberty to strike the heated iron with a small hammer between the blows of the large one, in order to keep it straight while being upset to form the head. When sufficiently hammered the iron is forced out of the die, and the head hammered into shape sideways and finished. A good workman, with a laborer for an assistant at the treadle, will make on an average from one to one and a half hundredweight of small bolts in a day. For large bolts enough of power could not be obtained in this way to upset heavy iron, and in this case a ring of flat iron is welded on the end of the bolt blank, and then hammered into shape.

For the coarser class of bolts, such as fish bolts for railways, etc., where strength is of more importance than superior finish, machines have been in use for some years. They are all of the same type; the bolt blank, being heated at one end, is placed in a die, and the heated part projecting sufficiently to form the head under steel heading tools operated by a crank, the pressure communicated to the header forces the heated iron into shape. It is obvious, however, that when sharp corners are to be produced, as in square-headed bolts, there is invariably a defect somewhere, probably from the sharp corners, as they are being formed, being most likely to cool first. For cup-headed bolts these machines make very fair work, provided always the iron is hot enough.

The defects of the two methods of manufacture are pretty numerous; in hand-made bolts there is the usual difficulty incidental to all hand work, want of uniformity in shape and size, and the quantity made is necessarily small; upon the other hand, the iron, if heated to a welding heat, is better worked by hand than with the machines mentioned above. It may be well to mention here that iron which has been brought to a welding heat, unless well hammered, deteriorates or goes back in quality, and this is a most important fact to bear in mind when manufacturing articles out of the smaller sizes of iron, when the heat is rapidly dissipated. The machines referred to above are not well adapted for this work, because the motion communicated from a crank to a header, either direct or by means of a lever, is slowest when it should be quickest; thus the motion is the reverse of what is required. The crank from the top center to half stroke gives the header an accelerating motion; the header will then have reached the top of the heated iron, to be pressed from this point to the bottom center; the crank gives a diminishing speed to the header while pressing the head into shape. The reduction of speed accruing from the motion of the crank has still another disadvantage; the die in which the iron is placed to form the bolt is usually kept cold by a stream of water playing upon it, and the heated iron is thus kept longer in contact with the cold die than it should be, and the iron has to be overheated in a proportionate degree to be sufficiently soft and plastic to form the head and neck properly; and here we have a liability to have the iron made short and crystalline from being overheated and not sufficiently worked afterwards.

In working small iron rapidity of motion is absolutely necessary, especially when square heads and necks have to be formed from round iron, and the quicker it is handled the better the result obtained. As we know that iron can be made hot by hammering it smartly while cold, so when heated to a high temperature the heat can be retained in the iron longer by working it rapidly. Of course there is a limit to this, and even conditions where it would not apply, as in the case of making a bar of iron longer and smaller, but in compressing iron, as in the form of a rivet or bolt-head, the statement is applicable.

A WEEDING MACHINE.—Our English exchanges contain accounts of a trial of a weed eradicator which took place under the auspices of the Highland and agricultural society. The object of the machine is to remove the weeds which grow among corn crops. A drum, about 24 inches in diameter, is placed between two carrying wheels. Three sets of projecting teeth or iron combs run horizontally along the drum. This, when the machine is in operation, revolves by the action of the gearing, the combs at the same time working in and out of the slits, and over and along the top of the crop. Supposing the ground to be soft, the teeth catch the weeds and pull them fairly out of the soil; but should the soil be hard, as was the case at the trial, and thus have a firm grip of the roots of the weeds, the combs tear off the heads, so that they are prevented from "seeding," leaving the stem in the soil. As the drum revolves and the teeth are drawn in towards the center, the weeds or their heads come in contact with the circumference of the drum, and not being pulled in at the slits are allowed to drop to the ground. The teeth exert little or no action upon the crops, the blades passing between the teeth.

MANAGING BELTS.—A mechanic gives the following directions for managing belts. He says: I have for the last 25 years on every Saturday evening turned the inner side of my engine belt outside, let the engine run slowly, and wash the belt well with warm water and soda, applied with cotton waste. Next I take a piece of sheet metal and scrape the belt well, then wash with clean warm water and dry off. I collect the waste oil from the shafting and apply as much of it to the belt as possible. The washing must be done as quickly as possible, so as not to dissolve the glued parts. I let the belt stand on the pulleys till Monday, then give another scraping and turn the belt as before. I keep the pulleys very clean. I have long been surprised at the economy I have effected within the last 10 years. There is an engine near me 14 inches by 36 inches (mine is 12 inches by 36 inches). I have nearly double the shafting and belt, and my neighbor cannot run with less than 38 pounds of steam when all the belts are on the loose pulleys. Mine will run at full speed with five pounds.

A SHOP COOLER.—To reduce the temperature in a factory in Paris, recourse was some time since had to an inexpensive form of air cooler, described as follows: A thin plate of metal, perforated with holes one-tenth of an inch in diameter, and having a total area equal to one-ninth of the surface of the plate, was set at a slight angle in a tight box; over this plate a thin sheet of water, at a temperature of 55 degrees Fah., was allowed to flow steadily, and by means of a power blower, air was forced into the box below the plate; by its pressure, the air forced its way through the holes in the plate and through the water, and was then led by pipes to all parts of the factory. By this device, the air in the room was reduced to 57 degrees. Other experiments gave varying results, according to the initial temperature of the water, but in each case the apparatus reduced the temperature of the current of air to within seven degrees of that of the water. Steam power is required for the blower, and for the best results, the supply of water must be abundant and its temperature low.

THE RUSSIAN AS A WORKING MAN.—In a paper read before the Paris society of civil engineers on the 5th ult., by M. Sergaeeff, the Russian workmen employed by him (in large soap works) are stated to be of quiet and peaceable disposition. The efforts made in other countries for the establishment of *cites ouvrieres* would have ample success in Russia, owing to the sociable character of the working man. In all large works the master finds his men a large house fitted with dormitories and a bread oven. The domicile is given up to the men, who form themselves into a copartnery and elect a manager who buys provisions wholesale, distributes them retail and gives in a monthly account checked by two auditors. The Russian workman is sober, eats little meat and lives principally on black bread and cabbage. His expenses, including washing, average 12s. a month. He puts by a little money for his clothes and his weekly bath, and sends some 12s. or 14s. home to his family. In the villages a communal constitution is found similar to that which is set up at any large works, and the men, used to obedience, are not scattered and lost among the corrupted masses of large cities.

A REMARKABLE CLOCK.—In one of the French papers we find a description of a wonderful piece of mechanism in the clock line. Here are the particulars: It chimes the quarters, plays 16 tunes, plays three tunes every 12 hours, or will play at any time required. The hands go around as follows: One, once a minute; one, once an hour; one, once a week; one, once a month; one, once a year. It shows the moon's age; the rising and setting of the sun; the time of high and low water, half ebb and half flood, and, by a beautiful contrivance, there is a part representing the water, which rises and falls, lifting some ships at high water tide as if they were in motion, and, as it recedes, leaves these little automaton ships dry on the sands. The clock shows the hour of the day, day of the week, day of the month, month of the year, and in the day of the month there is provision made for the long and short months. It shows the signs of the zodiac; it strikes or not, chimes or not as may be desired; and it has the equation table, showing the difference of clock and sun every day in the year.

RUSSIAN PRIZE ESSAY ON ENGINE AND BOILER MANAGEMENT.—The Russian technical society offers a prize for the best essay on the management of engines and boilers, drawn up in Russian, in a popular style, for the instruction of mechanics, stokers, engine-drivers and others. The mathematical acquirements of its readers are to be supposed as not going beyond a knowledge of the first four rules of arithmetic. Manuscript and printed treatises are equally admissible. The prize will consist of a medal and a sum of a thousand roubles (£154). Essays are to be sent in to the society by September 1st, 1878, at the latest.

SCIENTIFIC PROGRESS.

A Century of Astronomy.

Prof. C. A Young, of Dartmouth college, writes to the *Independent* a sketch of the American contributions to the science of astronomy during the century. We note the leading points as follows:

Since 1776 two great worlds, eight new satellites, 163 minor planets, some 40 periodic comets, and the meteoric hosts have been added to the rolls of our science. The physical connection of double stars has been demonstrated and investigated, the nature of nebulæ ascertained, and a whole body of most interesting facts in relation to the nature and constitution of the sun and stars and planets has been brought to light.

New and more precise methods of computation have supplanted the old. The power of telescopes and the accuracy of angular instruments have been enormously increased, and the art of observation has been correspondingly improved; while new inventions and appliances have opened new lines of research, before unimaginable.

To this great advance our own country has made her contributions. Not so great, indeed, as those of England, France or Germany, nor so great as she ought; but still enough to obtain for her a place and honorable mention in the history of science.

It is only within the

Last 40 Years,

However, that as a nation we have done anything for astronomy. In 1836 the first observatory in the country was built at Williams college; and in 1837 the second, by Professor Loomis, at Western Reserve college, in Ohio.

In the field of theoretical and mathematical astronomy we make, perhaps, the poorest showing. In the department of practical astronomy our record is better. Of the modern improvements in methods of observation, several, and those among the most important, are American. Of these we mention first the employment of electricity and the chronograph for recording the instant of an observation. This electrical method has worked something like a revolution, and diminished the errors of observation at least 50 per cent. in all cases where it is applicable. It is used at Greenwich, Paris, and Berlin—indeed, at all but a very few of the leading observatories of the world. It seems to have been invented in this country by several persons at nearly the same time (about 1848), the names of Walker, Locke, Saxton, Mitchell and Bond being all prominent in its early history.

Another capital improvement, due to American science, is Talcott's so-called "American method of determining latitudes," by means of the zenith telescope, or the ordinary transit instrument, fitted up in the manner first suggested and practiced by Professor Lyman. At present it is certainly more convenient and rapid than any other, and in accuracy superior to all, except the German method of prime vertical transits, which is, perhaps, its equal in precision.

Instrument Making.

In the building of telescopes and optical instruments generally our American makers are, to say the least, unexcelled. The number, magnitude and excellence of the great refractors made by Clark & Sons, of Cambridge, have secured them the first rank among opticians, and their instruments are now found in all parts of the world. The great telescope at Washington, and its sister, the McCormick telescope, as yet unmounted, are the two largest and finest refractors in existence. A few other large refractors have also been made by Fitz and Spencer, among them the instruments which, in the hands of Professor Peters, Watson and Langley, are doing such good work. In the line of reflectors we have done very little. The great Cassegrainian of 28 inches aperture, constructed by Dr. Henry Draper, of New York, is the only one of much power in the country.

As regards the

Number of Discoveries

Made by American astronomers within the last 30 years we stand fairly. In 1848 the seventh satellite of Saturn (Hyperion) was discovered by Professor Bond, at Cambridge, and in 1850 its so-called dusky ring. About a dozen comets have been first seen on this side of the water, and the keen eyes and indefatigable industry of Burnham and others have added some hundreds of double stars to our lists. In the search for asteroids, however, the greatest success has been attained. Of the 163 at present known, 47 were discovered in this country. France also claims 47, Germany 40, England 19, and other countries 10.

In the country we have about

Thirty Observatories,

More or less perfectly equipped, for the most part, indeed, better armed than manned; but among them the great establishments at Washington and Cambridge may be reckoned as two of the most effective in existence, fairly in the same rank with Greenwich, Paris and Pulkowa. Some half a dozen other observatories, also, though not so continuously active, send out good work from time to time, especially those at Clinton, Ann Arbor and Allegheny City.

If we look to the future there is fair ground for hope that our nation during the coming century will assume her rightful place as a cultivator of science. All signs seem to point that way. To be sure, there must first be a great change in the spirit and temper of our students and in the estimate of purely scientific work by the community at large. But the change seems to be already begun. An increasing number of our young men are willing to take the time needed for thorough culture and prefer the pursuit of truth to the getting of money. Some of our men of wealth, also, are finding in science a career and opportunity for honorable distinction more satisfactory than any other.

Lightning Freaks.

On June 7th a violent thunderstorm occurred at Valbonne, a large plain at a little distance from Lyons. The only objects struck were huts full of soldiers and arms, and the occurrence furnishes a good instance of the "power of points" and the attracting power of metals and living beings for lightning. Three tents were struck in succession. The occupant of the first was absent at the moment, and the effects were relatively slight, producing only the breaking of stones and dispersing of dust. In the second instance a soldier who was standing erect in front of one of the tents was struck; but the tent being located in the vicinity of an electric telegraph the lightning escaped by it, fired the wires, and broke a dozen poles. This may suggest a very easy method for protecting an encampment. The third flash struck a number of tents placed in a zig-zag line, doing much damage, several of the occupants being either killed or wounded. In one tent three men were killed and seven wounded. All of them were either touched in both legs or on the right side except one, who was wounded in the right eye. In another tent four men were wounded, all of them in both legs or in the left one. In other instances men were turned round in or heaved out of their beds. In all the instances referred to the men were lying on their beds, made of iron, and the sentry standing in front remained unhurt. In one tent a man, who was lying between two men who were killed, escaped unhurt. The uniforms of the soldiers were perforated and exhibited small spots; one, four centimetres in diameter, entirely sulphurized. A chemical analysis will be made of this part of the uniform, and the result communicated to the academy of sciences.—*Nature.*

A METAL MORE FUSIBLE THAN TALLOW.—M. Lecoq de Boishaudran, whose recent discovery of the new element, gallium, we have mentioned, has recently, for the first time, succeeded in obtaining a grain and a half of the metal in a pure state. This has enabled him to determine the remarkable fact that gallium melts at 85.1 deg. Fah., so that it liquefies when held in the hand. When solid, the metal is hard and resistant, even to a few degrees below the melting point. It can be cut, and possesses a slight malleability. When fused, it adheres easily to glass, on which it forms a beautiful mirror, whiter than that produced by mercury. It oxidizes but very superficially when heated to redness in the air, and does not become volatile. The density at 59 deg. Fah. is 4 7, that of water at 39.2 deg. Fah. being one. Excepting mercury, which only becomes solid at 37.9 deg. Fah., there is no other element which liquefies at so low a temperature as gallium. Fusible alloy of one part lead, one part tin, and one part bismuth, melts at 201 deg., and phosphorus at 111.5 deg. Wax and tallow have melting points respectively at 142 deg. and 92 deg. Fah.

SPONTANEOUS COMBUSTION OF COAL.—While cases of spontaneous combustion in bituminous coal are not of an uncommon occurrence, it is quite rare in hard or anthracite coal. The theory generally entertained is that the presence of pyrites in soft coal presents exactly the desired elements which by oxidation produce heat sufficient to develop combustion. There is every reason to believe that the sulphurets do materially assist in producing combustion, although cases have been found of coal heaps on fire where an analysis of the coal showed but the faintest traces of sulphur. It is now believed that soft coal, like charcoal, when finely divided and damp, absorbs oxygen on exposure to the atmosphere, and forming carbonic acid, develops heat. The inspector of Nova Scotia recommends, then, that coal for long voyages shall be put on board dry and in as large lumps as possible, so that the area of coal surface exposed to the action of the air and moisture may be as limited as possible.

VENEERED DIAMONDS.—Quite a notable industry is now carried on in Paris, namely, the manufacture of what are termed veneered diamonds, the method of production being briefly, according to the following fashion: The body of the gem is of quartz, or crystal, this being considered the hardest and best substance that can be made available for the purpose. Then after the crystals are cut in proper shape, they are put into a galvanic battery, which coats them over with a liquid, the latter being made of diamonds which are too small to be cut, and of the clippings and cuttings that are taken off of diamonds during the process of shaping them. In this way, all the small particles of diamonds that have heretofore been regarded as comparatively worthless, can now, by means of this ingenious French process, be made quite serviceable in the jeweler's art.

New Incorporations.

Tha following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

AGENDA M. Co.—Aug. 5th. Location: Butte county, Cal. Capital stock, $10,000,000. Directors—Silas Selleck, Daniel E. Hays, H. B. Congdon, Jas. Speers and Wm. Cooper.

LEXINGTON CON. M. Co.—Aug. 5th. Location: Gold Hill, Nev. Capital stock, $10,000,000. Directors—John Hagin, John F. Meagher, George W. Hayes, C. B. Edwards and H. W. Black.

KENTUCKY RINOR M. Co.—Aug. 5th. Locatinn, Nevada county, Cal. Capital stock, $3,000,000. Trustees—B. A. Becker, Martin Jones, James E. Byrne, G. S. Johnson and Joseph Snyder.

CENTENNIAL M. Co.—Aug. 8th. Location: Placer county, Cal. Capital stock, $1,000,000. Directors—John Keiser, John M. Greenleaf, William Edwards and E. G. Hinkley.

RESUMPTION G. & S. M. Co.—Aug. 9th. Location: Nevada. Trustees—John H. Thomas, O. C. McCracken, R. W. Jones, Mark Shephard and W. S. Foster. Capital stock, $10,000,000.

PYRAMID LAKE M. Co.—July 26th. Locatiou: Nevada. Capital stock, $10,000,000. Directors: Seth Cook, Daniel Cook, W. F. Myers, Wm. M. Lent and F. Osbiston.

MELBOURNE M. Co. — Location: Nevada. Capital stock, $10,000,000. Directors—Oscar R. Jones, E. R. Warsaw, S. N. Putnam, R. G. Bush and E. F. Stone.

PINE LOG C. M. Co.—July 24th. Location: Tuolumne county. Capital stock, $3,500,000. Directors—T. Don Carlos, Columbia, Cal; Ashor S. Taylor, John A. Robinson, William Walsh, S. E. Holcombe, San Francisco.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

RICH CLAIM — Amador *Ledger*, Aug. 5: G. W. Kling has owned a mining claim at Amador City, adjoining the Keystone, for many years. The rightful ownership has been tha subject of dispnte for a long tima, involving Kling in considerable expense. He has now, however, obtained a clear title to the property, and contemplates an earnest prosecution of work forthwith. He was offered $32,000 a few days ago for one-half interest in the mine, which he refused. The claim has nht been developed to any extent. A body of ors, we believe has been struck, but the value of the property arises from its proximity to the Keystone, and tha fact that a rich ore body has been worked in tbs Keystone to the boundary line of Kling's mins.

THE PHŒNIX MINE.—Men are now at work putting in 20 additional stamps to the Phœnix mill, which will bring it to 80 stamps, giving it a crushing capacity of 160 tons of rock per day, which as far as we know, is equal to any mill in the State. The mine is able to keep this enormous crushing power constantly at work. The outlook for the town of Plymouth is particularly bright. The development of the Phœnix is every now and then damanding the employment of more men about the mine, and so stimulating business of every kind.

THE BONANZA MINE.—It is with pleasure that we are able to state that this mins—the hope of Drytown—is developing finely. The result of the recent sinking operations has exceeded the sanguine expectations of the owners. The shaft is now down about 120 feet, and the ledge has widened to between eight and ten feet. The rock is estimated to averege at least $10 per ton. We are told that in the light of a candle the free gold may he seen shining along the sides of the ledge. The 10 stamp mill is kept constantly running, crushing about 20 tone per day.

EXTENSIVE OPERATIONS AT VOLCANO.—Amador *Dispatch*, Aug. 5: We nnderstand that the Water company of Volcano are now making arrangements for the extensive working ont of the bottom of the Volcano flat. It will reqnire a large amount of capital to effect this proposed work, but if it is carried out there is but little doubt but what it will bring a return of old '49 days to the crator town, and prove very remunerative to the projectors.

BUTTE.

A LUMP.—Croville *Mercury*, Aug. 4: Ons day last week while the men were at work in Hendrick's claim they washed out a lump of gold valued at $100. Many beautiful pieces of gold are taken out of this claim. Befors the bedrock is cleaned up the coarse gold is scattered about on every sids, a rich and most beautiful sight.

GOLD.—C. P. Powers cleaned up on the West claim one day last week $1,950 after 20 days' run of ebont 10 hours each day. It is an easy mattor to guess jnst what thia claim will pay, its returns are so constant. A day more or less in the running time will show tbs same result at the clean-up.

HEAVY YIELD.—On Saturday last, Col. Abbey, of the Spring Valley compsny, witb a small detachment of men armed to the teeth, arrived in town from Cherokee, bringing two gold bricks, valued at $60,000, the result of a clean up after a run of 25 days. Tbis is about the same amount that was brought in less than a month ago from the same mines. It is doubtful if there is another mine in the State where ths returns are more constant than at Cherokee.

RIVER MINING.—A company bas been formed for the purpose of mining the bed of Feather river, where former operations showed the deposits to be very rich, the ground of the company embracing the old and famous Cape claim of 19 years ago. The present company propose to rock the deposits in the bed of the river, not by building a furnace, as river mining was formerly carried on, but by commencing a shaft on the bank of the river at a point opposite the last and richest workings of the former claims and above high water mark, and sink the same below the bedrock underlying the original gravel bed of the river; to run on upward incline drift from the bottom of the shaft throngh the bedrock into the gravel bed, and then along on the surface of the bedrock where the most valuable deposits are alwaya found. The company claim the bed of the river for ons and one-half miles above the Oroville bridge. Tbs capital stock is $5,000,000, divided into 100,000 abares.

CALAVERAS.

PROGRESS AT THE LAMPHEAR.—Calaveras *Chronicle*, Aug. 5: The new pump at the Lampbear mino was put into the shaft and set in motion last Monday. Everything works splendidly, and taken altogether there is not a more snbstantial, better constructed piece of machinery in tbe county. The pnmp, which is a six-inch Cornish, with a four-foot atroke, is of sufficient capacity to admit of sinking to any deptb desired. Tbe mine was freed of water Tbursday, and it is expected to complete some little necessary repairing to the shaft by Monday, when sinking will be commenced. Messrs. Reed, Maloney and O'Neil have contracted for sinking the shaft 100 feet despar, wbicb will meke it 200 feet in all. Tbe mine is now well supplied with all the appliances necessary for working to advantage, having separate hoisting and pumping machinery, and we confidently look for developments of a favorable character in the near future. Tbe machinery lately erected was put up under the snpervision of Mr. John Rider, and the satisfactory manner in which it works adds to his reputation as a first-class mechanic.

HAULING ROCK.—Tha work of hauling rock from tha Quaker City quartz mine to the Lamphear mill has been commenced. A contract has been let for delivering 500 tons.

UPPER COUNTRY MINING JOTS.—Champion, at West Point, sinking. Shaft down 208 feet. Ledge, two feet thick. Tha richest ore ever taken from the ledge is now being mined. Reports from the Bliss Rica continua favorable. Splendid ore is being taken out and the prospects that the pay chute is extensive are favorable. The new mill at the Josephine will be ready to start next Monday. A large quantity of first-grade ore is on the dumps. Fields & Co. have resumed work. At Mosquito, Garland's mill is still running on rock from the Stockton mine. A new pump has been put into the San Bruno and the water taken out of the shaft. Active operations are to be pushed forward. Good ore continues to be taken from the Lewis & Fairchild mine, in tha vicinity of Alabama hill. The prospects of the mine are first-rate. The pump in the Grasshopper broke Thursday, necessitating suspension of work until another casting could be procured.

INYO.

ECLIPSE MILL AND MINE.—Inyo *Independent*, Aug. 5: Since our last mention thereof, there has been added to the Eclipse property extensive water works, which are intended to protect the mill from fire as well as to supply the surrounding buildings and provide for some irrigation. It is forced into a tank extending entirely across the extreme top of the mill, 60 feet in length. This is fitted with plugs and a supply of 2-inch hose, by means of which any part of the mill can be deluged. The mill fixtures have been improved by the addition of machinery for the saving of free gold. An extra boiler has been put in for steaming the amalgamating pans, a thing more essentially necessary in cold weather. The works will resume operations about the middle of the month, and from the improved appearance of tha ore now being extracted from the mine, the most satisfactory results are anticipated.

THE KEARSARGE.—Quite an exciting strike was made in the Kearsarge mine this week. This was the opening of a body of ore assaying no less than $2,000 per ton. Our only information as to its extent is that it is "a large body." The mill has not yet started up on a regular run, but will in a very short time.

THE HOLT MINES.—The prospects in one of the mines Mr. J. H. Holt is operating upon on the east face of Kearsarge mountain, near the summit, are very fine. This week they opened an eighteen inch ledge, assaying from $500 to $600 per ton. Kearsarge mountain will bloom yet.

LEE DISTRICT.—*Coso Mining News*, Aug. 5: From Mr. Pater Taylor, superintendent of the Emigrant mining company, we learn that work is steadily progressing and the prospects looking brighter every day. The ore now being taken from the center shaft, near the cabin, is richer than any yet taken from the mine, while on the north shaft the ore will average $500 per ton. Thirty-seven tons now ont on the dump of this shaft is pure, black, brittle silver and not a dozen shovelfuls of waste. As soon as the shaft is down 75 or 100 feet, a drift will be run connecting both shafts, when great developments are expected. We also learn that plenty of water has been struck to run a 20-stamp mill. It will be no trouble to bring the water to the mine, and steps will immediately be taken to lay pipes carrying between five and six inches of water, when we anticipate large shipments of pure bullion.

EAST MODOC CONSOLIDATED.—We are informed that Mr. Walsb, superintendent of the East Modoc consolidated mining company, will arrive in a few days and start work on this company's mines. Mr. Walsb is a scientific and practical miner.

NEW SUPERINTENDENT.—Archie McDonald will arrive from San Francisco in a few days and go to Lee district to superintend the South Emigrant consolidated company's mines.

MENDOCINO.

GOLD NEAR UKIAH.—Mendocino *Dispatch*, Aug. 5: It's no new thing to bear about gold near Ukiah—at Calpells some few miles above our town—as gold was taken out of the ground there frequently, several years ago, at ons time in some paying quantities. But a new move has been made, and we understand things are now in such a shape that water will be brought to the gold section and everything done to work the diggings to some purpose. Quite a little excitement bas started up, and the lately sleeping and quiet town of Calpella begins to exhibit signs of a great awakening and noise and bustle. A new hotel building is in progress of erection, property is finding purchasers, and visitors are looking at and talking of the prospects. We wish the new move good speed and success, for while such result would immediately benefit Calpella and vicinity, it would largely help Ukiah and its surronndings. Parties acquainted with this gold section express the belief that it is extensive, and only requires water, a scarce article there part of the year, to make it pay out well. We hear that an expert bas been examining and reporting favorably; that new parties, in connection with Mrs. DeWolf, are taking an interest in the new movement; that a lerge amount of lumber has been spoken for; that a ditch or flume of some miles in length is to be made to furnish water; and that a large amonnt of work is to be started and pushed forward. We do not vouch for all this, but it's a matter of certainty that there's gold there, from what we hear a good showing of it, and the move to open it up and bring it into use seems to be a live one. Outsiders need not be in a hurry to rush in yet though, but bad better wait for a little more information.

MONO.

BENTON.—Cor. Inyo *Independent*, Aug. 5: Mr. Hoyt bas been appointed superintendent of the Indian Queen company, and arrived in town yesterday. This company suspended milling operations about two months ago, but will resume work next week, under very favorable circumstances. The operations will probably give employment to all the idle men now around our town. The Comanche company is doing well; the value of its bullion shipments amounts to $1,200 daily, with a certainty of increasing that average during this month.

PLACER.

MINING ITEMS.—Dutch Flat *Forum*, Aug. 3: As stated in our last issue, the water season is fast drawing to a close. Only a few claims continue washing, and the miners are already commencing to rig for the next season. The Polar Star claim runs during the daytime, and the same head of water is used nights by the Minera ditch company and Staple Bros. The Franklin, Lacamp and Boston are washing a few hours each day. The Indiana Hill and Cedar claims, at Gold Run, continued washing till Monday morning, at which time they both turned off to clean up. The Yankee tunnel is still being worked with vigor. The tunnelers had worked about 10 shifts, fired nine face shots and advanced 28 feet; making a total for the month of 46 shifts, 37 face shots and an advance of 160 feet. The total distance run to date, from the mouth to present face, is 1,666 feet; the distance yet to be run in order to reach the Baker shaft is 866 feet. The Baker, or third shaft, which bas been worked thus far by one shift of men, is now being sunk more rapidly, as three shifts were set to work on the 1st.

TAYLOR MOUNTAIN COAL.—Sonoma *Democrat*, Aug. 5: The work of prospecting the coal discovery in Taylor mountain, near Santa Rosa, has been vigorously pushed during the past month. We are glad to say that it is now almost certain that the coal exists there in paying quantities. The incline is into the hill to a depth of 85 feet, and the width of the vein at that depth is eight feet. Samples taken by us yesterday from the shaft are superior to any before obtained. It is a lignite of very superior quality, with now and then a strata through it of true mineral coal, which makes an excellent coke. If, as not at all unlikely, the lignite turns at greater depth to a true coal vein, the discovery will be the most valnable yet made in this line on the Pacific coast. Some of the best quality was retorted in the coal-gas works of this city with unexpectedly favorable results. We await with lively interest further development.

TULARE.

PLACER MINES.—Visalia *Delta*, Aug. 3: Considerable excitement prevails in Visalia over the reported discovery of rich placer diggings on Mill creek, about 40 miles from town. As is nenally the case, various wild runiors are afloat concerning the richness of the discovery. Some 20 or 30 of our citizens have gone with the crowd, but none as yet have returned to confirm the reports. So we must await for more definite information before entering into detail. The N. E. tunnel and smelting company promises the miners of Mineral King to have a smelting furnace in operation sometime during the present month. This is the one thing needful in order to prove the value of these mines. It must be demonstrated that the ore can readily be reduced by some practical process, and that process must be determined before the mines will assume any real and permanent importance.

TUOLUMNE.

HYDRAULIC MINING. — Cor. Tuolumne *Independent*, Aug. 5: The Remington mining claim, at Yankee hill, is in full operation, working night and day. This is the most extended hydraulic mining operation ever carried on in this district before. The company are washing gravel which could not be made to pay, worked upon that system in which the placers here have been worked heretofore. Therefore, if this proves a success, we may be correct in saying that there are acres of unbroken hills scattered over our county, containing large deposits of gravel, that will pay equally as well, if not better, than the ground the Remington company is now working, if worked in the same manner. When a man is heard to express a belief that there are tons of gold stored up in the hills and mountains of Tuolumne, that man is set down as being insane and a fit subject for the lunatic asylum. But we think this character of men about as insane as Gen. Sherman, when he quit his peaceful vocation at New Orleans and started for the war, saying, "Let us have 1,000,000 of men in the field—they will be needed to crush out the rebellion."

Arizona.

MORE BULLION.—Arizona *Miner*, July 28: Col. Bigelow and Mr. Mulvenon brought in from the Turkey Creek furnace, on Wednesday, 116 pounds, avoirdupois, of refined silver bullion, unassayed, but evidently considerably finer than .900, taken from a portion of the ore from the Peck tunnel. We saw this bullion in two *planchas* at Andara & Rowe's store.

A NICE PROSPECT.—Dan. Hatz, yesterday, showed us a prospect which he horned out of a pound and five ounces of rock taken from the south drift of Willis & Co.'s 65-ft shaft on the Victorine, on Oroom's creek, that excelled any thing we ever saw, in quantity of gold in proportion to the amount of rock, unless it was some picked specimens that showed a large amount of gold on the surface. This was rock broken right ont of the ledge by Dan. himself, and not selected.

PARTIES lately returned from Big Bug, Lynx and Groom's creeks, report the miners all in high spirits, though water is low. They say the Messrs. Elliott have struck a bonanza in the Accidental mins, on Lyon creek. Some parties, whose names we failed to learn, have lately discovered a ledge on the Verde road, a short distance beyond the slaughter house, and are taking pay ore out of a shaft they are sinking by the roadside. The ore is free gold and very rich. The ledge has been driven over for years by those driving in and out of Prescott on this road. Mr. Dills is in from the Peck mine, and reports the prospects fully up to anything hitherto shown in that wondor of richness. Mr. George Opdyke also writes to members of the company here, that it is rather improving than otherwise, in the quality and quantity of rich ore that is coming out.

Idaho.

ALTURAS ITEMS.—Cor. Idaho *Statesman*: The different quartz companies are working with their usual energy and perseverance, fully determined to show to the world the immense wealth of these Atlanta mines. Since my last letter, James Baxter & Co. made a very rich strike in the Leonora. I examined some of the ore, and without fear of contradiction say it is the richest gold rock discovered, with my knowledge of the many rich strikes in the Alturas mines. The Buffalo mill and furnace are on the road from Kelton and will reach the bar in about two weeks. In a few days the company will have a force of men repairing the old road, there is nothing doing to the new wagon road, as yet it is very doubtful if anything further will be done this year. We regret this very much as it is of the greatest importance to me. The old pioneer and locator of the Atlanta mine, Mr. John Simmons, cleaned up from the spring run in his placer claim about 500 ounces of gold dust.

NOON YIELD.—Mr. George Richardson came in from Atlanta Wednesday night. He has been at work on the Last Chance lode since the 7th of January up to the same time in May under a lease. He has worked equal to five men during this time; sometimes four and sometimes six men. They have taken out 22½ tons of rock, which has been crushed by Col. Baxter in the old Mattingly mill. The Colonel has given this mill a thorough overhauling and it is now doing good work. The 22½ tons yielded $2,800. Besides this, they took out rich specimens and pounded them up in a mortar and got $2,000 more, making in all $4,800. The lead runs from two inches to a foot in width. It pays about as much, four inches in width, as it does a foot wide. Judge Heath and the Newton boys, owners of the lead, are now working it. They are down 100 feet. Mr. Richardson says it is the best poor men's lead in the camp, for the rock is easily reduced and they always make more than expenses. Col. Baxter works this rock within eight per cent. of its assay value, and all the rock he works gives great satisfaction.

Montana.

GLEN CONCENTRATING WORKS.—Butte *Miner*, July 27: The Glen contrating works started up yesterday as an experiment, and concentrated nine tons of low grade copper ore taken from the Hattie Harvey mine, into three tons. This is good news to the many who are interested in the copper mines of this camp, as their dumps, containing large quantities of ore running under 20 per cent. copper will now become valuable, while heretofore it has been considered only as a waste.

SUSPENDED OPERATIONS.—Within the past few days two of the best mines in Butte have, for want of a market to dispose of their ores, closed operations. The Hattie Harvey copper mine—one of the richest and most thoroughly developed leads of its character in this camp—after spending a large amount of capital and labor in sinking and timbering a shaft, in running levels and connecting them by a winze, and in taking out nearly 1,000 tons of ore; besides erecting the necessary buildings at the mouth of the shaft and in putting up a whim, have now discontinued work until the ore already upon the dump can be sold. The moment a market can be found, this mine, in its present condition, could raise to the surface from 10 to 12 tons of ore daily. The other mine, the La Plata, is a silver-bearing lead. This lead, after being pretty thoroughly developed by sinking of shafts, running levels, etc., in the accomplishment of which it has been demonstrated that the ore showing is greatly above the average, while in spots there has been found, taken out and sold, some quartz that sampled nearly $500 to the ton, has, owing to the reason above given, and to the consequent small inducement offering to continue operations, ceased work, with a large supply of high grade ore on the dump. This company being perfectly independent and free from debt can afford to wait until mills are erected or increased facilities for shipping have been secured, but the general effects resulting to the camp will be bad.

Nevada.

BELMONT DISTRICT.

EL DORADO SOUTH.—Eureka *Sentinel*, Aug. 4: A gentleman just arrived from Belmont reports an immense strike in the El Dorado South. The whole district was in a blaze of excitement over the discovery. Our informant says the mill of the company went into operation a week ago. If this information is correct, lively times in Belmont may be anticipated before long.

CORNUCOPIA DISTRICT.

PROSPECTS.—Cor. *Silver State*, Aug. 5: Our town is improving, and things look now as though we might have a good cramp. Money will be easier after the 10th or 12th—next pay day—The Leopard company have struck it big, and their mine will prove one of the largest on the coast. They have enough good ore now out and in sight to run the mill a year. Contracts have been let so they can work on wood instead of sagebrush all next winter; and if bullion gets up to par you will see more money in this camp than there has been for a long time. The other mines are prospecting well. I saw Geo. W. Tucker, an old prospector, in this section. He is working the Fissure, and tells me it is looking splendidly. Most all the boys are getting their Ebenezer up, and have gone to work with a will, as they think ont dark days are over. I hope so—for all know we have had dull times long enough.

ELY DISTRICT.

LOCAL REVIEW.—Pioche *Record*, July 30: Owing to the closing down of the Alps mill and the Raymond & Ely mill not having started, the bullion shipments for the past week only amounted to $1,584. The stoppage of the Alps mill was caused by the Raymond & Ely pump ceasing to run. It stopped for various repairs, and it will probably be a week longer before the pump will be again started to work. In the Raymond & Ely mine prospect work on the various levels is still continued without variation, and will so continue for the present without developments are made above the water level. The Meadow Valley hoisting works are progressing as rapidly as possible, the appearance of the work in progress and the number of men at work, presenting the appearance of a beehive to the spectator. Chloriding in the mine still continues without apparent change. The main shafts of the American Flag and Pioche mines are being sunk pretty rapidly, but as yet have developed nothing important. The Alps mine is extracting ore, but it is not shipping any bullion owing to the mill being closed down. The Huhn & Hunt and Washington & Creole mines still continue working with their same force of men and are doing fair in the extracting of ore. In regard to the smelting furnace to be built by the citizens, no further progress has been made than the subscribing of $5,000. A project is now under way to build a furnace and concentrator at Bullionville, for the purpose of working the tailings of the Raymond & Ely company at that place. Good business men have the matter in hand and will push it through to completion and success. The present outlook of mining affairs present a dull front.

EUREKA DISTRICT.

THE RICHMOND YIELD.—Eureka *Sentinel*, Aug. 2: It affords us much pleasure to be able to state that the Richmond is one of the most productive mines in Eastern Nevada. Glancing over the Assessor's books yesterday we ascertained that the gross yield for the quarter ending June 30th, was $215,582, returning a net profit of $56,222.73. This was the result of less than two months' smelting, as the furnaces were not all set in motion until after the beginning of May. With the present immense bodies of high grade ore in the mine we may reasonably expect still better results in the futurs.

HAMBURG MINE.—A few days ago the air became so bad at the ore body in the Hamburg mine that it became necessary to run a drift connecting the chamber with the south shaft for the purpose of ventilation. The connection will be made in a few days, when the work of taking out ore will be resumed. There are already about 200 tons of high grade ore on the dump. With the exception of the three prominent mines on Ruby hill, the Hamburg promises better than any mine in the district.

ADAMS HILL.—The work of sinking the main shaft in the Wide West is progressing steadily, and a prospecting drift is being run north at the 300-ft level. The shaft is down 370 feet, and the drift above mentioned is in vein matter the entire distence with occasional bunches of ors, which indicates close proximity to a chimney.

SPANISH BELT DISTRICT.

QUICKSILVER.—Belmont *Courier*, July 29: The quicksilver discoveries of which we spoke last week as having been made in Spanish Belt district seems to be of more importance than was at first supposed, though nothing has been done yet in the way of actual development. Seven locations have been made of 1,500 feet each. On the Discovery claim (the Alahama) and the adjoining claim (the Sally Ann) the lode is from three to five feet in width, with an ore streak from six to ten inches in width. The highest essay of the ore, which is a true cinnabar, yet obtained is 15 per cent. and a fraction, and the average about eight per cent. All the essays so far have been made of float ore and croppings. Float and small streaks of ore have been found at various points for more than a mile from the Discovery claim. Those who are familiar with quicksilver mines and their characteristics assure us that all the indications are favorable.

WASHOE DISTRICT.

HALE & NORCROSS.—Gold Hill *News*, August 3: The old pumps have been taken out and the new ones put in to within 300 feet of the surfaces. This finishes the shaft work up to that point, so that it will not now take long to complete it to the surface. The new boilers are inclosed, and the steam connection being rapidly made with the pumping engins.

NORTH CON. VIRGINIA.—The erection of the new pumping machinery is progressing at a very favorable rate. Nearly all of the machinery is now on the ground and is being placed in position ready for use. The drain tunnel is also making good progress and is rapidly approaching the shaft.

JUSTICE.—Daily yield, 75 tons of ore. The ore breasts and stopes continue to yield fine ore. The east cross-cut on the 800 ft level is showing much more favorably, and there seems but little doubt but that the ore body will be developed much more extensively than on the levels above.

SAVAGE.—Taking out the old pump columns and inserting the new is going steadily ahead. Considerable trouble is being experienced in straightening and repairing the shaft before the new pumps can be properly placed. The new pumping engine has all the steam connections completed, ready to turn on steam whenever the pumps are prepared for work.

CENTENNIAL.—Work was resumed on this mine this morning, after some months suspension, on account of the general depression in mining matters.

LEVIATHAN.—The new hoisting engine is working splendidly. The new blower for driving air into the lower levels of the mine is completed, and is also working finely.

BELCHER.—Daily yield, 300 tons of ore. The ore breasts continue to yield well. The prospecting drifts in the southern portion of the mine are steadily advancing, with much more favorable indications than for some time past. The erection of the new pumping machinery is also going rapidly ahead.

CHOLLAR-POTOSI.—Daily yield, 100 tons of ore. The

assay value of the ore is about $32 per ton. Sinking in the main incline is steadily progressing at the rate of three feet per day.

PHIL. SHERIDAN.—Shaft down 274 feet. The flow of water is still quite strong. The ground at the bottom works well.

CONSOLIDATED VIRGINIA.—The extraction of ore for the past month has been light, owing to the extension of the main shaft from the 1500 down to the 1550-ft level, the repairs that are being made in other portions of the mine, and the want of greater milling facilities. The results, however, are amply sufficient to insure the payment of the regular monthly dividend of $2 per share. The prospecting drifts south on the 1400-ft level started up during this intermission and are again developing rich ore, showing conclusively that the ore body extending in that direction is far better than it has heretofore been supposed to be. On the 1500 ft level, going south, almost exactly the same character of work is being done, with precisely the same results, showing that the mine has an almost incalculable amount of rich ore yet to extract in that direction, without touching the lower levels, if the management so desires. The ore stopes on the 1500 and 1550-ft levels are still yielding rich ore, and show but little change in any direction. The cross drift from the main north drift on the 1700-ft level, running to connect with the bottom of the south winze below the 1550-ft level for air purposes, is making steady though slow progress on account of the great heat. Preparations are being made to tap the water in the bottom of the winze with diamond drills, and thus avoid accident or delay. The rebuilding of the old pan mill is going rapidly forward, the placing of the machinery being now well advanced. The completion of this mill will insure a sufficient crushing capacity to enable both the California and Consolidated Virginia to continue their present dividends, and even increase them, if they so desire, for an unlimited length of time yet to come.

CALIFORNIA.—Daily yield, 700 tons of ore. The ore stopes extending north, upward and to the eastward on the 1500-ft level are all showing richly. The ore breasts on the 1600-ft level are also opening up just as richly. The mills are kept steadily running, and the bullion yield for July will hug closely $2,000,000, not only permitting the payment of the usual dividend of $2 per share, but affording a large surplus to carry over to the August account. The mine never has shown richer than it does to-day. It is true that a few million dollars have been extracted, but it is also true that the ore developments made since the extraction of ore was commenced has more than filled the place of that taken out, so that we have not the least hesitation in asserting that the mine is worth as much or more than it was known to be one year ago. It is simply looking superb, with enough huge blocks of ore squared up, ready for extraction, to keep the mills running for a length of time almost beyond calculation. The pumping engine at the C. & C. shaft is again hoisting a perfect river of water, being kept running at the rate of 10 strokes per minute. It is steadily gaining on the flow, but has a mighty work to perform in doing it. The engines for driving the new battery mill are in place, the steam connections with the boilers are being made, the shafts lined up, the stamps placed in the mortars, and the general finishing touches are being administered preparatory to starting the whole into operation as soon as the Consolidated Virginia pan mill is completed.

OPHIR.—Daily yield, 300 tons of ore. Four mills are kept constantly crushing the ore, which is yielding better pay than it has done since the great fire in October last. The ore stopes are looking splendidly throughout the mine. The ore stopes on the 1600-ft level, going east, have improved very much during the past four days, the prospecting drifts going eastward at that point having cut through a strong horse of porphyry into a new deposit of very rich ore. The ore taken from this new discovery has raised the assay value of the car samples from $104 to $192 per ton during the past week. But what gives it the most valuable and permanent look is the fact that the same rich body of ore has been struck in an east winze, at a depth of 50 feet below the 1600-ft level, proving that it is extensive, and that the quality is even better at that depth than above. The prospecting drifts going north on the 1600-ft level are rapidly advancing toward the Mexican line, and are showing excellent indications of ore. On the 1700-ft level the north drift is being driven rapidly forward, following the east wall of the ledge toward the Mexican line, at which point it is the intention to again drive an east cross-cut through the ore vein. In the east cross-cut, 75 feet south of the shaft on the 1700-ft level, an upraise has been started to connect with the bottom of the east winze now being sunk in the east ore body below the 1600-ft level. Sinking the main incline is making excellent headway.

GOULD & CURRY.—The old pumping machinery is being taken out, and the foundations rapidly enlarged for the reception of the new and powerful machinery now in course of construction. The repairs to the shaft are going steadily forward. Sinking the joint winze on the Savage line is going rapidly forward, the bottom still in favorable vein matter and perfectly dry. The bottom of the winze is now over 100 feet below the level of the water in the Savage shaft. The winze is sinking in an entirely unprospected portion of the ledge, lying between the Savage and Gould & Curry workings. A drift has been started south on the 1700 ft level of the Gould & Curry to connect with the bottom of this winze. Colonel James G. Fair, the superintendent of this mine for the past two or three years, being greatly pressed with attentions required by his other mines and the arduous duties attached, has resigned the superintendency, and Colonel Frank Ashiston, late superintendent of the Savage mine, has been appointed to fill the vacancy.

ALTA.—The splendid new and powerful pumping machinery was started into full operation yesterday, and worked with the utmost perfection, draining the water from the shaft in less than two hours' time. This machinery has no superior on the Comstock in finish, strength and apparent adaptability for the purpose for which it is intended. The shaft is now down 430 feet, and the sinking has been resumed in the best of spirits. It is confidently expected that the shaft will cut the ore vein by the time it has reached a depth of 700 or 750 feet.

BULLION.—The week has been spent in trying to complete the connection of the bottom of the winze below the 1400-ft level and the upraise of the 1700 ft level, so as to get a circulation of air and ventilate the mine. Several fearful heavy blasts of giant and black powder have been exploded in too intervening ground without having yet accomplished the desired result. The workmen are so close together that they can distinctly hear each other walk and talk.

JULIA.—The main south drift on the 1600 ft level has shown a steady improvement during the past four days. The full size of the drift is in quartz of splendid character, which now assays $20 per ton, and shows every indication of opening into paying ore at almost any time. The east cross-cut recently started on the 1600-ft level, to cut the ore vein developed at the 1700-ft pump station, is also showing a decided improvement.

IMPERIAL CON.—The north drift on the 2000-ft level, running to connect with the Alpha, is making good progress. The north drift from the winze below the 2000-ft level has been stopped for the past day or two on account of an insufficient supply of air.

DAYTON.—Sinking the main shaft is going ahead, notwithstanding the flow of water at the bottom of the shaft still gives considerable trouble and prevents as good progress as would otherwise be made.

ROCK ISLAND.—The north and south prospecting drifts on the 850-ft level are again steadily advancing. Both are in ledge material.

WARD.—The rate of sinking the shaft has been increased to six feet per day. The south drift in the Julia, on the 1600-ft level, is fast approaching the Ward line, the face in ore steadily improving in quality.

HERALD.—The ore vein at the bottom of the incline is showing splendidly, the ore is widening and the assays are excellent. Many are of the opinion that the ledge is opening out into a veritable bonanza. The ore in the face of the north drift is also showing finely.

OVERMAN.—Sinking the main shaft is making the usual fair progress. The flow of water is still strong.

MEXICAN.—The face of the west cross-cut on the 1465-ft level, following the course of diamond drills used at that point, is now in fine ore. A cross-cut west has just been started, on the line of the Ophir and Mexican, on the 1600-ft level.

SUPERIOR.—Had to suspend operations on account of boiler repairs, and in 36 hours the water raised 100 feet in the shaft. Work going ahead all right again and water reduced to 18 feet.

EAST JUSTICE.—Work going ahead as usual, ground getting softer, which allows of considerable progress being made.

PROSPECT.—Total depth of shaft this morning, 441 feet. Sinking suspended for a few days until the station is opened at the 400-ft level. Considerable water is encountered, driving the pumps to their utmost capacity.

CROWN POINT.—The south drift on the 1700-ft level is still advancing toward the Belcher air shaft.

EUROPA.—The north drift on the 500-ft level is steadily advancing, the face in very hard rock. This morning the rock was softening somewhat, with apparent indications of an approach to the ore vein.

NIAGARA.—Sinking the main incline has been delayed somewhat during the past two days by the timbering of the shaft.

UNION CONSOLIDATED.—The north drift, following the west wall of the ledge on the 1300-ft level is looking very promising.

LADY BRYAN.—The surface work is being steadily pushed ahead without intermission. The recent cloud bursts washed away a considerable portion of a water ditch, which is now being rebuilt

TWIN PEAKS.—The surface grading is completed, and a road is now being made to bring in the requisite timbers, etc. Sinking the large new working shaft will be resumed shortly.

BEST & BELCHER.—Cleaning out and repairing the drifts and cross-cuts on the 1700-ft level preparatory to future operations is being steadily accomplished.

NORTH CARSON.—Good development work is being done in the mine, with considerable good ore in sight, and excellent prospects ahead.

CALEDONIA.—Sinking the shaft is going steadily ahead. The flow of water at the bottom is still fearfully strong, and keeps the pumps actively at work.

LADY WASHINGTON.—Sinking the shaft goes steadily forward in the same excellent vein material mentioned in last week's report.

SUTRO TUNNEL.—Total length of tunnel this morning 13,783 feet. Face of header in tough porphyry with streaks of quartz and clay.

MITCHELL.—Sinking the winze at the same good rate of progress, with very favorable vein matter and low grade ore in the bottom.

COSMOPOLITAN.—Good work being done in main north drift, which still shows plenty of good ore in the face.

Important to Settlers.

The following important bills have lately passed Congress and are laws:

Concerning Settlers and Public Lands.

An act to amend "An act for the relief of certain settlers on the public lands," approved December 28th, 1874, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That all the rights and privileges granted by an act for the relief of certain settlers on the public lands, approved December 28th, 1874, are hereby extended for one year after the expiration of the time named in said act. And all the rights and privileges extended by this act to homesteed and preemption settlers, shall apply to, and include, the settlers under an act entitled "an act to encourage the growth of timber on western prairies," approved March 3d, 1873, and the acts amendatory thereof.

Approved June 19th, 1876.

To Encourage the Growth of Timber.

An act to amend an act entitled "An act entitled 'An act to encourage the growth of timber on Western prairies,'" approved March 13th, 1874.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section three of the act entitled "An act to amend the act entitled 'An act to encourage the growth of timber on western prairies,'" is hereby amended by adding thereto the following further proviso: Provided further, That whenever a party holding a claim under the provisions of this act, or whenever making final proof under the same, shall prove by two good and credible witnesses that the trees planted and growing on said claim were destroyed by grasshoppers during any one or more years while holding said claim, said year or years in which said trees were so destroyed shall not work any forfeiture of any of the rights or privileges conferred by this act; and the time allowed by this act in which to plant the trees and make final proof shall be extended the same number of years as the trees planted on the said claim were destroyed in the manner specified in this section.

SEC. 2. That the planting of seeds, nuts, or cuttings shall be considered a compliance with the provisions of the timber-culture act. Provided, That such seeds, nuts, or cuttings of the kind and for the purpose contemplated in the original act shall be properly and well planted, the ground properly prepared and cultivated; and in case such seeds, nuts, or cuttings should not germinate and grow, or should be destroyed by the depredations of grasshoppers, or from other inevitable accident, that the ground shall be replanted or the vacancies filled within one year from first planting: Provided further, That parties claiming the benefit of the provisions of this act shall prove, by two good and credible witnesses, that the ground was properly prepared and planted in such seeds, nuts, or cuttings, and were so destroyed by inevitable accident in such year.

SEC. 3 That it shall not be necessary to plant trees, seeds, nuts, or cuttings in one body, provided the several bodies not exceeding four in number, planted by measurement, aggregate the amount required and in the time required by the original and amended act.

Approved May 20th, 1876.

The Engineer.

A New Panama Route.

It looks as if a long art had been rediscovered in the way of getting across the isthmus of Panama by canal. According to the Panama *Star and Herald*, a citizen of Colombia, named Gogorza, has been making a tour of investigation up the river Tuira and its branches, the result of which has been to revive a project 200 years old, touching the feasibility of a canal route across the isthmus. Mr. Gogorza is so sanguine of success in establishing the new route, and has so convinced others of the importance of doing something about it, that there have been a number of conferences between Colombian magnates, the outcome of which is a message to congress from the president of Colombia urging that attention be given to the subject. Authority is asked for Gogorza's undertaking a careful and thorough survey, in order that the question of practicability may be definitely answered. This survey Gogorza offers to organize and prosecute at his own expense, and under arrangements which will relieve the matter of all uncertitude. The proposition is to go over the proposed route with a corps of engineers who, within the current year, shall accurately survey the region indicated, and then, upon their favorable report, a stock company can be gotten up in Europe of sufficient capital and influence to complete the canal in less than 10 years.

Subsequent explorations have confirmed the opinion that this route contains more promising possibilities than any other that has been proposed. What with the river itself and a series of newly discovered marshes on the direct line, it is believed that a canal could be constructed without compelling the construction of any locks, and thus the two rivers which pierce the isthmus on either side may be so connected by a cut through the marshes now lying between them as to give an uninterrupted water route from ocean to ocean.

Of late years, particularly, there have been a number of costly attempts to solve the Panama problem. It may be that the solution lies in the direction indicated two centuries ago and now urged again upon public attention. At all events we shall know all about it very soon, and meanwhile may hope that at length the project of connecting the Atlantic and Pacific oceans on this continent is soon to become as much an accomplished fact as is the junction between the Indian and Atlantic oceans by means of the Suez canal.

The Progress of the Jetties.

According to an article in the New Orleans *Bulletin*, the average depth of the channel between the jetties is considerably over 20 feet, the greatest depth being 25½, and the least 19. Altogether there are 28 soundings taken. Of these only three were as small as 19 feet, three of 19½, four of 20½, six of 21, four of 22, three of 23, three of 24, and the rest running 24½, 25, 25¼, and 25½ feet. Something remains still to be done. There is some shallow water inside the river end of the jetties, and this must be deepened ere the channel which Captain Eads' plock and science have given us can be until zed to its full extent. The suggestion has been made that the government dredges at Southwest Pass should be used for this purpose, seeing that the jetty channel is in all respects a better and more practicable one than any that ever has been or ever can be produced by the means at the disposal of the engineer department. But, some weeks ago, when the suggestion was first made, objections followed to the effect that the success of the jetties had not been demonstrated, and that by removing the dredges from Southwest Pass the government would be sacrificing a secure channel in favor of a mere experiment. Since then Captain Eade has worked on quietly and confidently, and in the interval many vessels have grounded in Southwest Pass, while many vessels of equal draught have passed safely and expeditiously between the jetties. Nothing now remains save to remove a narrow and comparatively insignificant bar lying above the head of the works. When that shall have been accomplished, the long-desired consummation will be attained, and New Orleans will rejoice in a permanent deep water channel to the sea. The jetties are steadily and rapidly deepening the water within their influence, and no reasonable doubt can be entertained as to their complete and triumphant success.

A POINT IN FAVOR OF DEPRESSION.—In his address before the mining engineers, at Philadelphia, on the 1st of June, Mr. Bell said that times of depression in trade, such as the world generally is suffering from, are beneficial to science, inasmuch that they enable manufacturers to pay more attention to processes, and effect economies in production, which they have neither the time nor the inclination to attend to in periods of great demand.

BRIDGES.—A writer in the *Railway Age* claims that the long illustrated article in the "Encyclopedia Britannica" on the subject of bridges is worthless. He says: The practical engineer need only look it over, to see that it is worthless for his purposes, but the unprofessional man, who has a right to expect precise and accurate treatises in a work having the high reputation of the "Encyclopedia Britannica," might easily be misled.

Tunneling Detroit River.

The Detroit correspondent of the *Railway World*, writing of this subject, says: Gen. Sooy Smith has been here in consultation, at different times, with a committee of council relative to the tunneling of the Detroit river. While Gen. Smith is confident that the project is feasible, he says that in self-defense he must decline to lay all his plans and specifications before the public and explain them in detail. He has one or two occasions been defrauded of his just rights and had his own engineering skill taken advantage of by others by a too free public exposure of them. But he would lay everything before any commission of competent engineers that the city might name, and he would be willing to abide by their decision as to the feasibility of his plans. He would submit his estimates to a commission of experts in the same way. He did not ask any voice in the naming of these commissioners, but had so great confidence in his estimates and in the practical character of his scheme that he was perfectly willing to rest the whole subject with any unprejudiced and competent body of men.

He said he had been engaged upon public works as a civil engineer for 25 years; had built railroad and other bridges over navigable streams. He knew the cost of such works and he would say with reference to his tunnel that it should be double tracked, and that he would guarantee that it would cost but very little, if any more, than a first-class double-track bridge. He supposed that so far as the city was concerned, it desired to foster both the railroad and the vessel interests, and to avoid all antagonism between them, if possible. It seems to be conceded that the railroads want and ought to have a better crossing here. To this the vessel interest do not object, providing the crossing be made so as not to interfere with them. Therefore a tunnel seems to be preferable to a bridge, as harmonizing both interests. A tunnel would be preferred by all if it could be built as cheaply as a bridge. He would undertake to build one, as before stated, at a cost which should not greatly exceed the cost of a bridge. He would agree to furnish the tunnel and approaches complete at his own expense, and to the satisfaction of any competent committee of experts, provided the work would be taken off his hands when completed. He could command the capital; in fact, it is already urged upon him, and he would not ask a cent of the city until the work is done.

He would commence in the middle of the river and build in both directions, and estimated that it would thus take about two years to complete the tunnel and its approaches. He called attention to the fact that this is an exceedingly favorable time to carry on a work of this kind. The money at his command is lying idle. The expenditure of so considerable a sum here would be of value to the city, both in a business point of view and in the employment of a great number of workmen. All things considered, there could be no more favorable time to undertake an enterprise of this kind. The various railway magnates interviewed by the correspondent of the *Railway World* favorably endorse the project.

MEMORIAL TO AN ENGINEER.—A bronze statue of the late James Carmichael, the celebrated engineer, from the chisel of Mr. John Hutchison, R. S. A., was on June 17th unveiled in Dundee, in presence of a great concourse of spectators. The ceremony was held on the centenary of the birth of Mr. Carmichael. Sometime ago the idea of erecting a statue to perpetuate Mr. Carmichael's memory was mooted, and were so warmly taken up by the leading citizens that the necessary funds were speedily procured. Mr. Carmichael was the inventor of the fan-blast and of many improvements in mechanics. The statue end pedestal rise to the hight of 17 feet. Mr. Carmichael is represented in sitting posture, examining a plan, with miniatures of his inventions on the plinth. The statue is erected on the grounds of the Albert institute.

A NEW DRAWBRIDGE.—A recently patented drawbridge, designed to afford perfect facilities for crossing navigable streams without impeding navigation, is the invention of Lieut. Com. H. H. Gorringe, U. S. N., of Washington. The bridge is composed of a number of floats, each pivoted or hinged at one end, the other and being moored to anchor piles by means of a chain passing over a windlass on the swinging end of the draw or leaf. By revolving the windlass the draw or leaf may be swung clear, so as to afford vessels a single passage as wide as the length of the draw; a reverse motion of the windlass closing the draw and opening the roadway. Since this operation may be performed with either or all of the floats, vessels may pass through the bridge at any point selected, or the whole width of the river may be thrown open to navigation. The inventor, among other things, claims "cheapness and facility of construction, greater security than ordinary bridges, freedom from obstruction to navigation, and from risk of damage by freshets, moving ice and other floating bodies."

THE ST. GOTHARD TUNNEL.—At the close of April, the St. Gothard tunnel has been pierced on the Goeschenen side to the extent of 10,263 feet. The corresponding progress effected at the same date on the Airolo side was 9,830 feet. The aggregate distance pierced April 30th, 1876, was thus three miles, 4,253 feet.

(Continued from Page 106.)

wave; and from the crater of Kilauea a collection of curious lava formations most wonderful in variety of colour and shape.

Beside the sugar cane, 15 feet long, we find the samples of sugar from crude to double refined, and a large glass case is filled with hats, mats, fans, flowers and delicate vases, made from arrowroot plant. All these articles are so odd and beautiful that they attract much attention, as do also the ancient idols and war clubs, the exquisite corals and tropical stuffed birds in a mossy recess, each bird looking alive on its own branch.

The botanist of our party lingers wistfully over the queer silver-sword plant that grows 12,000 feet above sea level, and, if I understand rightly, it is found nowhere else.

The ancient poi calabash, the venerable, painted water gourds, and similar native relics, offer quaint contrast to the handsome cabinet work now turned out by the islanders. The samples of native fabrics are very interesting, especially the Tahitian cloak, made from bark of the bread-fruit tree, and trimmed with shells; also the grass petticoat fringed in different colors of tree bark.

Queen Emma

Makes her special exhibit of right royal feathers, polished ware, bark cloth and various articles of historic value to the nation or the royal family.

Then the coils of native rope, the jars of clear oil from castor bean and candle nut tree, the pictures of wonderful scenery—"The information furnished to all who wish to acquaint themselves with the manners, customs, resources, government and civilization of the

Hawaiian Nation,"

All these things I mention merely to give a hint of the articles our Pacific neighbor has brought to spread before the world, and to quicken the interest of those who care for her welfare. No words can give a true idea of this bright and beautiful island nook where visiting faces all beam with that delight which comes from a "good surprise;" and as changing thousands still go trooping through, peering this way and that, amused, instructed and stimulated, there will be no need at the end of six months to ask the timid question,

"Will it Pay?"

Now, where shall we go when we leave the Sandwich islands? Tending westward we naturally bring up at China and Japan, and that is just what happened here in the main building as we go on and find ourselves in the midst of shining tea-trays and cabinets, large vases covered with impossible dragons, and all the fans, fabrics and fine needlework that have so long been familiar in San Francisco.

I asked some visitors what they considered most interesting of all they had found, and they said: "O, we have found nothing else so wonderful as the departments of China and Japan. Did you see the lovely, oriental ware, and the silk goods and that cunning Chinaman all dressed in his own clothes?"

"Yes, I passed through and saw the ladies, whole crowds of admiring ladies, sweetly smiling on that big, fat Chinaman; and I just wished California had sent along a few thousand of those 'conning Chinamen all dressed in their own clothes' so that this Centennial celestial need not be spoiled by too much admiration." (Perhaps we Californians are a trifle bitter on this subject. Eastern people seem to think we are.)

We had expected to find natives from everywhere "dressed in their own clothes," but with the exception of a few Turks and Japanese in their bazaar buildings, and the fat Chinaman in the main building, the great crowds day after day are "cut and trimmed" after pretty nearly the same pattern. They tell us it was not so at first, but that foreigners who began to go about in odd-looking rig were so annoyed by

Rude Boys and Respectful Reporters,

They finally laid aside their peculiar costume and disguised themselves in the ready-made clothing of Market street.

And now as we go on, a queer old rhyme keeps spinning through my brain—

> "Dr. Foster's a very good man—
> Whips his daughters now and then.
> When he whips them, makes them dance,
> Out of Scotland into France,
> Out of France and into Spain,
> Dr. Foster whips again."

When these lines were written they had reference to some deep political plot and to some great "power of the period" that held the reins and made persons and events dance to please him. But many an old verse has been mistaken for prophecy and what could come truer than the free-and-easy dancing "Out of Scotland into France, and out France into Spain?" That is just what we are doing here in a daze of almost speechless admiration and urged onward by the whip or spur of an eager curiosity.

When tired almost to death we still go a little further—"Out of Scotland into France"—and when the glory and glitter of Paris, the gilded-edged profusion of everything elegant and costly wearies the eye and brain beyond endurance, we still whip on and step through the grand Spanish archway that leads to a display, magnificent and even "gorgeous," perhaps, but not so large and dazzling as that of France.

Spain has also a separate building, large and well filled with treasures of art and science; precious old keepsakes left over from the age of immortal Don Quixote; fine collections of photographs of Spanish beauties, and of the royal family, who are not beauties; samples of some very big mahogany trees to show us how that lumber looks in the rough; and pictures old and new to show us the look of ancient and modern Spain and her most famous Spaniards. If you should go into this Spanish house tomorrow you might not even notice these things I have spoken of, because there are so many others equally attractive. Now that I come to think of it, the whole center of the building is filled with tables covered with maps, showing mountain elevations, water courses and all the minute geography of the country, and other tables hold models of forts and bristling armaments, well guarded by fierce soldier-statues armed from head to foot. Many of the old treasures would have been more interesting if the descriptions had been written out in English.

But I have been most astonished at the exhibits made from

Far Away Corners of the Earth,

That have never yet made much claim upon the world's admiration.

My California cocoon suffered over and over again a total collapse, as I found provinces of Australia, and almost unknown countries of Africa, and far away forgotten islands represented here by well filled departments; and not only well filled, but fairly brimming with beauty and interest. From almost countless objects demanding attention and giving the delight that always comes from a novelty that is agreeable, we look upward to read on silken banners the names of departments: "Tasmania," "Trinidad," "Gold Coast and Orange Tree State," "South Africa," "Queensland," "Mauritius," "Mozambique," etc. I was so delighted with the productions, pictures and politeness I found in Tasmanie, that I shall begin my next letter right there.

Useful Information.

Making Wax Fruits.

Many of our lady readers will doubtless wish to try their hands at wax fruit making this summer and the following on the subject from the *Journal of Chemistry* may be of assistance:

Closely allied to wax flower making is that of wax fruit, some specimens of which are marvelous for the faithful imitation of nature. Here molding or casting is of more importance than in flower making, seeing that accuracy of form is the chief desideratum. Most kinds of imitative fruit are shaped in double molds, one for each half, and, if the fruit is irregular in its curvatures, a tripartite mold may be needed Say that an orange is to be imitated in wax, a smooth, damp surface of sand is prepared, into which exactly one-half of a good orange is carefully pressed. A cordon or border of tin or stiff paper is built up around it about half an inch distance from the orange on all sides; plaster of paris in a cream-like consistency is then poured into the cell thus made so as to fully cover the orange; when quite firm enough to handle, this plaster half-mold is taken up and the orange extracted; the orange is turned over in the sand and another half-mold is made in a similar way. Whether fruit is cast solid or hollow, depends mainly on the size; if large the mass would be heavy and much wax wasted by solid casting; in this case a core of some rough material is fixed in the middle of the mold, which gives a cavity to the middle of the fruit.

Soft kinds of fruit, such as plums, cherries and ripe pears, and some hard and unyielding fruits, require special management to extricate them from the half-mold without injury to the fruit on the one hand or to to the mold on the other. Pomegranates; medlars, pine-apples, etc., require molds in more than two parts Occasionally elastic molds of glue are found advantageous. Generally speaking, the color of the wax employed is that of the lightest parts of the fruit, the deeper tints being afterward laid on with brush and pencil. The chief pigments employed are such as burnt and raw umber and sienna, chrome yellow, red lead, prussian blue, carmine, lake, etc., greens being produced by various mixtures of blue and yellow.

Certain small varieties of fruit, such as grapes and currants, are made of glass bulbs, carefully blown to the proper shape; these are fixed by wax to wire inserted into holes, and then dipped into melted wax of the proper color, a very thin coating of which gives the proper kind of semi-transparency to the glass and at the same time a smoothness of surface not inaptly resembling that of the natural fruit. The fastenings of the various fruits to imitative stems, leaves, leaflets, etc., is an affair of wires, silken thread, strips of green paper, white flock, arrow-root-paste, gum-mastic, varnish, with other simple materials and tools used in artificial flower-making.

Analysis of Ancient Bronze.—A fragment of an ancient bronze sickle, found with other articles in bronze in Anhalt, four feet down in the ground, has been tested by G. Kranse. It was found to consist of 90 parts copper and 10 tin, without the smallest trace of arsenic, antimony, lead, zinc, iron, or nickel. According to Quenstadt, zinc indicates a Roman origin for bronze, lead a Greek origin, and nickel a Keltic. As the object tested by Kranse belongs to the so-called bronze age, it appears as if tin was known in very early antiquity.

Hints for Work.

Cockroaches may be driven away by putting Scotch or other high-dried snuff around their haunts.

Dean or engraved silver goods should never be cleaned with plate powder, but be washed out with a soft brush and some strong alkali, and well rinsed afterwards. When the dead or fostered parts are quite dry, the polished parts are carefully cleaned with powder.

Boil linseed oil, 60 parts, with litharge, two parts, and white vitriol, one part, each finely powdered, until all the water is evaporated. Then set by. Or, rub up borate of manganese, four parts, with some of the oil, then add linseed oil, 3,000 parts and heat to boiling.

A rod of brickwork=272 superficial feet, one a half bricks thick, or 4,350 bricks average work. One yard of paving=36 bricks flat or 52 on edge. There are 384 bricks to a cubic yard, and 1,000 bricks, closely stacked occupy about 55 cubic feet.

An English correspondent of the *Saddlers' Gazette*, writing from Philadelphia, says: "In some shops English varnish it solely used for the finishing coat, yet the best painted carriages in the whole exhibition are those whereon American varnish has been used exclusively."

Heavy Leather.—A firm in Boston have lately received some remarkably fine large and heavy sides of sole leather. Two of them weighed severally 112 pounds and 105 pounds, and measured nearly 11 feet in length, and the thickness of them ranged from five-eights to one inch. They were made from the skins of Calcutta buffaloes.

The best means for producing a black surface on brass, pinobheck or silver, is said to be platinum chloride, which is allowed to liquefy by exposure to the air. It is rubbed in with the finger, or best, with the ball of the thumb. After blacking, the object is washed and polished with oil and leather. Platinum chloride is dear, but a little of it will do a great deal of work.

Crane chains, says the *American Manufacturer*, should once in a while be taken off and thrown into a furnace until red hot, then brought out and be kept in a compact pile and permitted to cool slowly. Better still, let them remain in a furnace after coming to a heat and then to cool off with the furnace. Where a furnace cannot be had for the purpose, they can be heated in a large wood fire and then be permitted to cool as slowly as the fire is dying. Being thus annealed they are safe.

Varnish Brushes.—All varnish brushes ought to be made of long white hairs of the best quality, and, for the general purposes of varnishing, have a good regular spring, with about one-fourth or fifth part worn off flat, sharp, and thin at the point, so as to lay on the varnish smoothly and regularly. As the beauty of varnishing depends in a great measure on the brush, as well as the manner of laying it on, great care is also necessary that no *oil brush* be put into vernish; therefore, all brushes worn down in oil color, and intended to be put into varnish, ought previously to be well washed in turpentine, squeezed and dried with a clean linen rag, or well washed with soap and hot water, rinsed in clean warm water, and made perfectly dry. The best method of keeping oil varnish brushes, when not in use, is to bore a hole through the handle, and put a wire skewer through it, and so suspend the brush, in a narrow tin pot containing varnish of the same sort as it was last in, taking care that the varnish in the pot covers the hairs of the brush up to the binding, and no higher. Brushes so kept are always straight, clean, pliable, and in good order; whereas, varnish brushes kept in turpentine become hard and harsh, and however well stroked or rubbed out, there will still remain turpentine enough to work out by degrees, and spoil the varnishing, by causing it to run streaky or cloudy.

Good Health.

Cultivating the Appetite.—There are few housekeepers who are not at one time or another perplexed beyond measure to provide acceptible food for guests. One does not eat butter, another declines potatoes, still another refuses mutton, a fourth cares nothing for fish, a fifth eschews pastry, and the hostess can but suffer mortification and annoyance in seeing one dish after another that has been prepared with care refused without good cause. A very polite principal of a young ladies' school was in the habit of frequently saying at meal time: "It is aristocratic to eat lamb; all my young ladies eat lamb." As a matter of fact, it was the most healthful and the most expensive meat he could procure at certain seasons of the year, and he considered it an important part of their education that his pupils should learn to like all varieties of wholesome food. These were accordingly provided, and the best of dietetic habits formed. His example is certainly a good one for heads of families to follow in training children. Various circumstances often restrict diet to half a dozen articles of food, and if these some are rejected from mere caprice, serious inconviences often follow, while only pleasure and advantage result from a genuine liking, though it be the offspring of cultivation, for all kinds of nutritious and wholesome food.

How to Cure Cuts and Stings.

We find in the *Prairie Farmer* some hints concerning treatment of small wounds. In every home there ought to be a place known to all the members of the household, but out of reach of the children, set apart for things which are likely to be wanted in case of accident. These should include a pair of good scissors, three or four large needles, ready threaded, some broad tape, a little lint, a roll of clean old linen, flannel and calico, part of each of which should be torn into slips, some sticking plaster, goldbeater's skin, turpentine, lunar caustic (nitrate of silver), tincture of arnica, and tincture of calendula. The possession of these articles will enable any one who can act with self possession and nerve to deal promptly and wisely with most of the every-day accidents to which flesh is liable.

Cuts

Cuts require to be treated suitably according to their position and character. A cut finger is best tied up in a rag with the blood; for blood is very healing. If a cut has any foreign substance, such as glass, gravel or dirt in it, this should be removed by being bathed in lukewarm water before the rag is put on. If a cut is severe, the blood should be examined. If it is dark, and oozes slowly from the wound, it comes from a vein, and is not serious, if it is bright scarlet, and spurts out of the cut like water from a fountain, it comes from an artery, and a doctor ought at once to be sent for. Until medical aid can be procured, the wound should be tightly bound, and the artery should be tightly pressed above the wound and nearer the heart. If the skin gaps from the cut, the edges should at once be brought to their proper position with calendula plaster. If in a little time it begins to throb, the plaster should be removed, and the rag moistened with calendulated water; it is most useful for wounds where the flesh is deeply cut or torn. If a little lint is soaked in it and put upon the wound, it will in nine cases out of ten prove most beneficial. It is made by mixing thirty drops of the pure tincture of calendula, which may be bought of any chemist, with a half tumblerful of water. A cut on the head requires great care. The hair should be cut all round the place, and lint dipped in calendulated water be laid upon it. As long as the first dressing of a cut remains mains firm and gives no pain, it need not be touched.

Slings from Insects.

After being stung by a wasp or bee, the first thing to be done is to remove the sting. This may be done with a pair of small tweezers, or the sides of the wound pressed with a small key, so it may be squeezed out. Then apply to it immediately spirits of camphor, sal volatile, or turpentine, or failing these, rub it with a little common salt, or a little moist tobacco or snuff. If a wasp or a bee stings the throat, a little turpentine should be immediately swallowed. If the place swells very much and looks inflamed, it should be bathed with arnica, or have a hot white-bread poultice laid upon it. The arnica may be made by mixing twenty drops of the pure tincture with half a tumblerful of water.

Eating Fruit.

The earlier in the day fruits are eaten the better; they should be ripe, fresh and perfect, and eaten in their natural state, with the important advantage of its being almost impossible to take too many; their healthful qualities depend on their ripe acidity, but if sweetened with sugar, the acidity is not only neutralized, but the stomach is tempted to receive more than it is possible to digest, and if cream is taken with them, the labor of digestion is increased; hence the fearful attacks of cholera morbus which sometimes follow the free use of fruits and berries with sugar and cream.

No liquid of any description should be drank within an hour after eating fruits, nor should anything else be eaten within two or three hours after—thus time being allowed for them to pass out of the stomach, the system derives from them all their enlivening, cooling and opening influences. The great rule is, eat fruits and berries while fresh, ripe and perfect in their natural state, without eating or drinking anything for at least two hours afterwards. With these restrictions, fruits and berries may be eaten in moderation during any hour of the day, and without getting tired of them, or ceasing to be benefited by them during the whole season. It is a great waste of lusciousness that fruits and berries, in their natural state, are not made the sole dessert at our meals for three-fourths of the year; human enjoyment and health, and even life, would be promoted by it.—*Hall's Journal.*

Bathing.—Cold baths, if taken at all, should be taken in the morning, when the body is invigorated by a night's rest; and then it is well to use water that is of the same temperature as the air, and not freshly drawn from well or cistern. Baths taken at night should be about the same temperature as the body, and warmer, if they give the slightest chilly feeling.

Onions for Children.—A mother writes: Once a week invariably I gave the children a dinner which was hailed with delight; this was a dish of boiled onions. The little things knew not that they were taking the best of medicine for expelling what most children suffer from, worms. I believe mine were kept free by this remedy alone.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 mos.	12 mos.
Per line..... .25	.80	$2.00	$5.00
Half inch (1 square)...$1.00	3.00	7.50	24.00
One inch..... 1.50	4.00	12.00	40.00

Four weeks are rated a month.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, Aug. 12, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Academy of Sciences; Notices of Recent Patents; Improved Railroad Axle Lubricator, 105. A Plea for Inventors; Comstock Papers, 112. Facts About Peat; A Manufacturing City; Opening of the Mechanics' Institute Fair, 113-16. Mining Accidents, 116. Patents and Inventions, 117.

ILLUSTRATIONS.—Side Sectional View of Railroad Axle Lubricator and Dust Excluder; End View View of Lubricator, 105. Pittsburg—View from Coal Hill, 113.

CORRESPONDENCE.—Alpine County—Its Mines and Resources, Past, Present and Future; Mechanical Ore Concentration and Separation; Gems and Precious Stones; Centennial Chat, 106-111.

MECHANICAL PROGRESS.—Bolts and Screws; A Weeding Machine; Managing Belts; A Shop Cooler; The Russian as a Working Man; A Remarkable Clock; Russian Prize Essay on Engine and Boiler Management, 107.

SCIENTIFIC PROGRESS.—A Century of Astronomy; Lightning Freaks; A Metal more Fusible than Tallow; Spontaneous Combustion of Coal: Veneered Diamonds, 107.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 108.

MINING SUMMARY from various counties in California, Nevada, Oregon, Montana, Idaho and Arizona, 109-10.

THE ENGINEER.—A New Panama Route; The Progress of the Jetties; A Point in Favor of Depreciation; Bridges; Tunneling Detroit River; Memorial to an Engineer; A New Drawbridge; The St. Gothard Tunnel, 110.

USEFUL INFORMATION.—Making Wax Fruits; Analysis of Ancient Bronze; Hints for Work; Varnish Brushes, 111.

GOOD HEALTH.—Cultivating the Appetite; How to Cure Cuts and Stings; Eating Fruit; Bathing; Onions for Children, 111.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 116 and other pages.

MISCELLANEOUS ARTICLES.—Important to Settlers, 110. The Artisan (Poetry), 116.

THE WHEELER SURVEYING EXPEDITION.—The Wheeler expedition for the exploration and engineering survey of territory west of the 100th meridian, will leave Washington in a few days for another season's work. Lieutenant Wheeler will establish his rendezvous camp near Carson City, and four parties, one of them under his personal charge, are to make thorough surveys east and west of that point, and northward in the Sierras from Beckwith's pass as far as possible this year toward the Oregon boundary line. The intention is to connect with the western line of Wheeler's former work and the southern line of the survey. This portion of country has never been scientifically explored, and consequently no good map of it has ever been made. Two other parties of Wheeler's expedition are assigned to work in New Mexico and western Colorado.

CARPET MAKING.—The carpet manufactories of Philadelphia, we are informed from a census of that branch of industry taken by a leading establishment, employe 651 power looms and 3,499 hand looms. These looms have a capacity for producing annually 25,000,000 yards of ingrain and Venetian carpets.

NEW PLACER DIGGINGS.—A dispatch from Fresno says: Considerable excitement is caused by the discovery of some rich placer diggings on Mill creek, in the foothills of the Sierra Nevada, some thirty miles from here.

A BUILDING on the grounds of the Giant powder company, back of this city, was burned this week. No special damage was done beyond the loss of the building, which was valued at $500.

THE Hurricane Co., at Oreana, have started their furnace and are turning out about three tons of base bullion daily. Twenty tons of the bullion was shipped East to Newark, New Jersey, last week.

THE steel plant of the Bessemer steel works, St. Louis, has been started.

A Plea for Inventors.

[For the MINING AND SCIENTIFIC PRESS, by JOHN L. BOONE.]

Of all the mental efforts requiring imaginative construction none is more difficult than that which is required to develop a new mechanical movement, or originate a new plan, mode or mechanical principle. The faculty of inventing depends more upon natural endowments, or rather instinctive intelligence, than upon education and experience. Experience only figures in this connection so far as it serves to familiarize the inventor with the wants or deficiencies in any line of industry; and education assists in giving completeness to the conception; but the conception itself is a matter entirely independent of either, and is just as apt to be suggested by an illiterate and inexperienced person as by one who has spent years in studying and investigating the matter; in fact more so, because education and experience are both the result of study and long familiarity with existing devices, so that they, to a certain extent, incapacitate their possessors from looking beyond the boundary of their experience and teaching. Upon the principal that "fools rush in where angels fear to tread," the illiterate inventor will investigate methods and plans which many an experienced artisan or workman would not entertain for a moment, simply because they do not possess that imaginative construction necessary to give the new creation mental existence, and because their teaching and experience do not include the new ideas. Thus many of our most important and most novel inventions have been originated and developed by persons entirely devoid of technical knowledge and experience in the field of mechanics to which their inventions belong. Accident, circumstance and necessity all contribute to the discovery of new principles. Sometimes, however, we find the skilled and educated mechanic possessed of the inventive faculty, and when this is the case he proves a "world mover." Such was Ericsson, who did more to develop the engine and strengthen the navies of the world than all other inventors combined. Such was Morse, who, with a skill and learning which was admirable in its completeness, adapted and perfected the telegraphic system; with such precision and judgment that to-day it retains the principle features that he gave it. Such were Hoe and Colt, and other inventors whose memories the civilized world hold in reverence.

All patents are not productive—neither are all farms; all men are not rich; all mines are not bonanzas; but if we were to strike a balance sheet we would find that the proportion of the profitable and unprofitable patents correspond in a like ratio with the other profitable and unprofitable enterprises which men undertake.

When we consider the vast number of patented articles in the market, many of which are covered by a number of patents, we will realize that the work of the inventor is very often profitable. There is scarcely an article of human convenience or necessity in the market to-day, that has not at sometime or other been the subject of a patent, either in whole or in part. The sale of every such article yields the inventor a profit. If we purchase a box of paper collars a portion of the price goes to the inventor; if we buy a sewing machine the chances are that we pay a royalty to as many as a dozen or 15 inventors at once. Indeed the field is so vast and the number of profitable patents so great that I would by far prefer to undertake a recapitulation of those patents which are not profitable than those that are.

The universal sentiment is that genius is its own reward, and in order to give effectiveness to the sentiment the person who possesses genius in any branch of industry, is allowed to set his own price upon the result of his labors. It is therefore but a just recognition of the services of the inventor that he be allowed to provide for his own wants from the benefits which he confers upon the public. The artist who produces a picture of unusual merit can find purchasers for it at a fabulous price. The stage actor who can draw crowded houses can demand and receive for a single performance what would be a year's salary for an ordinary workman; and the lawyer that possesses the faculty of swaying the minds of a jury by his eloquence can demand and receive whatever sum of money he desires for his services, yet the labors of the inventor yield more substantial results, and benefit mankind more than all these combined. He is the sapper and miner who prepares the way and overcomes all of our mechanical difficulties; in fact he furnishes us with the honey, while we are drones in the hive that benefit from his labors. Give credit then where credit is due. The inventor is the world's benefactor, and as such we take off our hat to him.

THE English company's mill at Troy, in Eureka county, Nevada, has been sold to the Martin White company at Ward, for the very low price of $11,000. The original cost of the mill must have been more than $50,000.

THE Eberhardt and Aurora mining company, of White Pine, declared a dividend of five shillings per share, which was paid in London on the 10th inst.

Comstock Papers.

NO. 3.

An Error Corrected—First Samples of Ore that reached California.

We find, on conversing with certain of the early Washoe miners, that we erred in the last number of these papers, in saying that Comstock owned the most of the rich ground purchased by Judge Walsh, and that the property so bought was described as the Comstock claim in the deed of transfer made on that occasion. The facts connected with his first visit to Washoe, his return and subsequent purchases, as we have them from Judge Walsh himself, were these: Towards the latter part of June, 1859, B. A. Harrison, then keeping cattle on the Truckee meadows, brought some pieces of the rich Comstock ore over the mountains to Grass Valley, where the Judge was engaged in quartz mining. This ore had been given to Harrison while on his way to California by a man named Stone, with directions to take it over to Grass Valley and have it tested, its weight leading him to believe that it contained a good deal of metal of some kind or another. Stone, who resided at Stone & Gates' crossing, a well known locality on Truckee river, had been to the mines and there obtained this ore, and having a notion like many others, that it might be valuable, availed himself of the first opportunity that offered for having its character determined.

The Assay and its Results.

Judge Walsh, to whom Harrison had given these samples on his arrival at Grass Valley, took them to Melville Atwood, who was then carrying on the business of assayer at that place, and instructed him to make an assay of them, being himself satisfied that the ore was rich in the precious metals. Mr. Atwood made two assays from the same piece of ore and found it to contain $3,000 in silver and $876 in gold—a total of $3 876 to the ton. These assays, undoubtedly the first ever had of the Cometock ore, were made on the 27th day of June, 1859. The two buttons obtained and the pieces of ore from which the assay samples were taken, handsomely mounted and inclosed under glass, are to be seen in the office of Almarin B. Paul, of this city, with the certificates of Atwood and Harrison, attesting their genuineness appended thereto. There was residing in Grass Valley at this time Richard Killala, an accomplished Irish metallurgist, also several German assayers, all of whom were well acquainted with this class of ores, and readily divined the importance of the discovery, having had more or less experience in silver mining countries.

The Ophir Ground—How it was Held and the Prices obtained for it.

Encouraged by the opinions of these men and taking council of his own judgment, Walsh at once set out for Washoe, the name by which the region of country where this deposit had been found then first began to be known. Arriving at the spot early in July, the Judge remained there a week or more during which time he became so well convinced that this ore-find was likely to prove valuable that he determined to buy out some of the parties laying claim to it. In pursuance of this purpose he came home, supplied himself with money and at once returned, reaching the mines toward the latter part of July. By this time a number of locations had been made along the supposed line of the main lode, to which latter there had as yet been given no name. The principal of these claims consisted of the Ophir, embracing 1,500 feet, with the Central 150 feet; the California 300 feet, and the Central No. 2, 100 feet, adjoining it in the order mentioned on the south.

Finney's claim to the rich spot on the Ophir ground having been gotten rid of in the manner already narrated, that location was now owned by the following parties: (100 feet, afterwards known as the Mexican ground, having previously been disposed of.) Henry P. Comstock, Joseph Winters, Peter O'Reilly, Patrick Mc Laughlin and Penrod, each one-sixth; Theodore Winters, one twenty-fourth; Honseworth, one twenty-fourth and Osborn one-twelth. Judge Walsh bought Penrod's one-sixth, paying him $6,200 therefor; also Comstocke one-sixth paying him about the same amount, besides $5,000 for one-third of the California ground, and some small and unimportant locations he had made further south. In the early part of August, Morrison and Hurst bought out Mc Laughlin for $2,500. Later in the fall John O. Earle and Judge Walsh purchased O'Reilly's interest paying $36,000 therefor, the Winters having retained their interest for a considerable length of time. In all the purchases and sales made by Judge Walsh, as well as in the other operations carried on by him in Washoe, Joseph Woodworth was his equal partner.

The Mexican Claim.

As stated above, 100 feet of the original Ophir ground had been disposed of before the sales here mentioned were effected. This section, commencing 200 feet from the south end of the claim and embracing the richest portion of it, had been given by the joint owners thereof to Penrod, Osborn, and Comstock, as a consideration for two cheap arrastras that they had put up for the use and benefit of the company. Penrod, who owned one-half of this section, sold the same in October to the Meldonado brothers, for $3,000, the other half having been sold by Osborn and Comstock to Hughes and others for about the same sum. The Meldonado's being of Spanish origin led to this piece of ground being called first the Spanish and afterwards the Mexican claim. In the early part of 1861 the Meldonado's sold this ground to the houses of Alsop & Co., and Duncan, Sherman & Co., for $200,000. These parties failing to manage the property with much energy or good judgment, tired of the ownership and afterwards disposed of it to the Ophir company for $30,000. It now forms a part of the present Ophir mine.

First Arrival of Ore in San Francisco—Heavy Costs and Big Returns.

Early in the month of September, Judge Walsh came to San Francisco bringing with him 3,150 pounds of selected ore taken from the first opening made on the Ophir ground. This ore was worked by Mosheimer & Kustel, and netted him $4,871. The cost of transportation, there having been as yet no wagon roads built over the mountains, was, as a matter of course, very great. Later in this month, Walsh and his associates in the mine commenced the regular shipment of ore to the city, having by the first of November, when the snow rendered the mountains difficult of passage by wagons, sent down 38 tons, which, worked by the same parties, gave a gross yield of $114,000, exactly $3,000 per ton. The cost of freight and reduction on this lot was at the rate of $512 per ton.

The Washoe Excitement Begins.

This bullion, which was placed on exhibition in the banking house of Alsop & Co., first began to arouse the moneyed classes to the importance of this new discovery, and infect the popular mind with the idea of silver mining. A good many miners with some speculators, traders and adventurers in general, had already made their way over the Sierra Nevada, there having been gathered in the Washoe region a thousand or more of this class before the winter set in. The newspapers also, for several month's before had teemed with favorable accounts of the mines over there. But these had been generally regarded as exaggerated or over colored statements, such as usually emanate from excited and interested parties, and had therefore produced no very marked influence upon either capitalists, speculators or the working masses. The sight of this ore and the resultant bullion had the effect, however, to awaken up everybody, and before the winter was half over, thousands were making preparations to emigrate to the new land of promise.

Different Views Held by Different Parties.

Meantime, not a few who had secured interests in the new mines, being timid or acting under the advice of those preemned to be safe counsellors, hastened to dispose of the same, realizing often very inadequate prices. Among others accorded a high reputation for scientific knowledge and claiming a practical acquaintance with silver mining, but who still entertained a very poor opinion of this Washoe discovery, was the French engineer of mines, M. Lauer, sent out by his government to examine and report upon the gold mines of California. So little faith had he in this discovery that he advised his friends to part with their interests as soon as they could realize the smallest profits, his course in this respect having been practically endorsed by some of our resident experts who had enjoyed a long experience at silver mining in South America and in different parts of Mexico.

Among those who had visited and examined the deposits in the new district, few shared in the opinion held by these more learned men; and it is but just to say the early Washoe miners, notwithstanding they were so ready to sell out, professed the greatest confidence in the richness and permanency of the mines themselves; this seeming inconsistency being explained by the fact that they were all very poor, and wished to make a small stake at the first opportunity; every one of them believing, moreover, that he would be able, as soon as he had sold these first claims, to go and find others equally valuable. Messrs. Woodworth and Walsh relate, that while camping with Cometock, near the claim purchased of him, he pointed to the spot where Virginia City now stands, and declared his conviction that it would soon become the site of a great city, and that the mine he was about to sell them would yet turn out to be one of the biggest in the world. It is true, such expressions as these might be attributed to that spirit of gasconade in which Cometock was so apt to indulge, and through the exercise of which he afterwards succeeded in having his name applied to the whole of this Washoe lode; yet the prediction seemed, under the circumstances, so improbable that one regarding it as somewhat prophetic, feels inclined to credit these utterances as having been made with a degree of sincerity at least.

THE Secretary of the Treasury will probably sell about $2,200,000 gold early next week. The proceeds of the new five per cent. bonds which he will sell Saturday for account of the Geneva award, he will award as for gold, in sums not less than $500,000.

AN official call has been issued for proposals for five per cent. bonds of the funded loan of 1881, to amount to $2,160,000, to enable the Secretary of the Treasury to pay the judgments of the commissioners of Alabama claims.

Facts about Peat.

No. 2.

Written for the PRESS by SAMUEL PURNELL.

Neglect to Use.

Although peat is considered a good fuel, with few disadvantages, yet it has not come into general use because it could not be furnished as cheap as coal—except in a few localities, mostly on the continent of Europe. It has to go through a preparatory process, whilst coal is dug already prepared. The charcoal, however, which the substance furnishes, as a calorific agent, has been attested to be equal to coke, and superior to wood charcoal, by practical skill and theoretical calculations. Many attempts have been made in Ireland, Scotland, Holland and Germany to render peat suitable and profitable for manufacturing as well as domestic uses. The expense, however, has mostly defeated such attempts; and it was likewise found difficult to eradicate preconceived prejudices against this fuel; it is hard to learn anything new. Its use is yearly increasing in Germany, Hanover, Westphalia, Denmark, Russia, many parts of Austria, Italy, many parts of France, India and a few portions of the United States. In many of these places peat is a general article of consumption, superceding all other classes of fuels. Its merits have been subject to the closest scrutiny in Germany and France. In 1863 it was estimated that 359,310 tons of peat were consumed in France during the preceding year. The advance in the price of coal in Europe during the last few years has caused the use of peat to increase largely. Holland consumes about 40,000,000 tons annually. In Ireland peat has not yet been able to compete generally with English coal; nor has it in the United States with native coal. It is everywhere a question of expense only. But it is reasonable to assert that there are many localities in this country where the peat bogs would now be able to compete with inferior coals and those brought from great distances. The main point and difficulty is to produce a good marketable peat cheap enough, that is, at about half the price of good bituminous coal. It is believed this has not yet been done, except in rare cases.

Preparation.

In preparing peat for commercial uses, dozens of processes and hundreds of machines have been invented. Everything that human ingenuity could devise seems to have been tried What would be pronounced a success at one bog would be condemned at another; because, probably, of the different varieties of peat, and the varying circumstances under which the workings were carried on. The main idea was to *condense* it. Now, some peat can be readily condensed, and some not. Much peat is of a light and springy nature, and tends to fly back to its original condition when released from a press; and it is notorious that no success has been attained in attempting to compress this kind of peat. Machines have been constructed usually on the pug-mill principle, that of the brick machine. It seems necessary that all kinds of peat should be ground or cut up to some extent in order to free it from a part of its water, and, by breaking up its fiber, allow it to become hard and firm on drying, or permit of a more thorough condensation by machinery. It is believed that all successful machines have been operated on this principle. Most of these machines have failed from their liability to breakage or from insufficient quantity of product in a given time, or from inferior fuel made, or from the expense of the operation.

For Domestic Purposes

Peat that is elastic and firm may be simply cut out of the bog and dried in the sun without mechanical compression. When brittle and soft it should be ground with water. It is an agreeable household fuel. For manufacturing purposes, especially for metallurgical, peat must be thoroughly prepared, be dry, and all possible density be given to it. It is a problem how to dry peat into a hard solid substance simply by the air. Many efforts have been made to dry it artificially, but the result has always been a failure; not because of the expense only, but because it has been ascertained that peat is somewhat injured by artificial drying, and it afterwards re-absorbs the expelled moisture from the air, and this re-absorption causes the blocks of fuel to crack and lose their consistency. Exposure to the sun and air will generally dry this fuel sufficiently in any country, especially would it do so in the hot and dry climate of California.

Its cost as fuel is due almost entirely to the manual labor expended upon it. Though it may seem thoroughly dry, peat should not be piled solidly, for it is liable to a fermentive process from the moisture still remaining in it, and sometimes undergoes spontaneous combustion. Some old peat is semi-gelatinous, which, when dried, serves to cement the whole together. If this species of peat is compressed part of the gelatinous constituent escapes with the water involving a serious loss.

A Manufacturing City.

The illustration on this page is a view of one of the largest manufacturing cities of the United States—Pittsburg. It is the western terminus of the Pennsylvania railroad, and the point of junction with the Fort Wayne and Chicago, the Cleveland and Pittsburg, and the Pittsburg, Cincinnati and St. Louis railroads, and was, in

PITTSBURGH—VIEW FROM COAL HILL.

1870, the sixteenth city in the United States, and uniting with it Allegheny City, which in fact forms part of the same community, was the eleventh in the number of inhabitants, the two containing an aggregate of 139,526 souls It is built at the junction of the Allegheny and Monongahela rivers, which here unite and form the Ohio, and is particularly distinguished for its iron and glass manufactories, in these two industries outranking any other American center of industry. The capital invested in iron manufactories in 1870, was $26,962,686, and in the manufacture of glass, $4,000,000. It is also the center of an immense coal trade, aggregating over 5,000,000 tons a year. The vast manufactories centered here belch forth ceaseless clouds of smoke, and give it the popular title of the "Smoky City." At night, from the hills surrounding it, the view of these ceaseless fires, bursting luridly through the dense pall which overhangs the entire region, gives it a grand and peculiar appearance, unlike any other place in America.

The country surrounding the city is picturesque, characterized by rugged heights and deep valleys. These natural beauties have been enhanced by public and private improvements, and if they are marred by the smoke which rises from numerous manufacturing industries, their attractiveness is by no means obliterated or destroyed.

FROM all accounts Ward district, the young and prosperous mining camp, is attracting considerable attention from mining operators, both in California and the East. New mills are in process of erection and several furnaces are already completed. The camp is lively and the mining outlook of the district indicates permanent prosperity.

Opening of the Mechanics' Institute Fair.

The eleventh industrial exhibition under the auspices of the Mechanics' institute, was formally opened on Tuesday of this week. The opening exercises took place at Wade's opera house and were of a very interesting character, comprising music by 500 pupils of the high school, a fine orchestra and the Aimee opera troupe, with an address, oration and poem. The whole concluded with a tableau representing artisans at work at their trades.

The exhibition was opened on the same evening. As yet it is by no means in a complete state, although by Monday everything is expected to be in good order. The machinery department is not as well filled as it should be considering the character of the fair, although the whole exhibition will, when complete, give a good general idea of the state of our home manufactures. The pavilion presents an attractive appearance, being handsomely decorated. The music is good and the art gallery and horticultural garden form features which afford a great deal of enjoyment. We intend giving in the PRESS as full a description as practicable of all that is novel in the fair, paying special attention, however, to what will be of interest to mechanics and miners.

We append the opening address delivered by A. S. Hallidie, President of the Mechanics' institute, and also the poem written for the occasion by Mr. Soule. The oration by Mr. Henry Edwards, on "Iron and its Relation to Civilization," we are compelled to defer for want of space, but will publish it in full next week.

Opening Address of President Hallidie.

LADIES AND GENTLEMEN: The managers of the Eleventh Industrial Exhibition bid you welcome, that you may bear witness to the skill of the people and the handicraft of the sons of industry and toil, desiring that in the exhibition hall you may be not so much impressed with the gaiety of the scene, or by the pleasure it may give the eye, as that what you see there may create an estimate of values in your mind and having created, may build up an appreciation of these values that may influence you, and through you generations to come.

On the 7th of September, 1857, the first industrial exhibition was inaugurated in San Francisco, in a little building about the size of our present Art Gallery, erected on Montgomery street where the Lick house now stands and which, at that time, was considered rather far out of town.

Progress of the Exhibition and Institute.

Many of you have watched the progress of these exhibitions and the Mechanics' Institute with tender care, and from time to time have loaned money freely and without interest, to tide over financial requirements. Let me say to you, free-hearted and noble-minded citizens of San Francisco, that this generosity is neither forgotten or unappreciated.

Up to the present time ten industrial exhibitions have been held. Not possessing lands on which to erect buildings adapted to the needs of the exhibition, the managers have, from first to last, expended about $200,000 for temporary structures erected on leased ground.

When we reflect on the large sum thus outlayed, it seems singular that a permanent location has not been secured, and strange that these enterprises should have justified such large expenditures. This can be only understood when we remember that the people of San Francisco have always liberally supported these industrial exhibitions, and that the managers have given time and thought to the careful administration of affairs in connection therewith, voluntarily and without recompense.

But the time is near when it will be necessary to obtain a site on which a building suitable for these exhibitions can be erected for permanent use. In two years the lease of ground occupied by the Pavilion expires, at its present terms, an extension of one year being allowed by the payment of a bonus of $7,500.

It is believed, and hoped, that the present exhibition will relieve the managers of debt and enable them to refund to the public spirited citizens and corporations the balance due them on the loans they so generously made two years ago, for which no interest is asked and on which one-half, so far, has been reimbursed, leaving an indebtedness remaining of $29,064.63.

Value of These Exhibitions.

It is difficult to estimate the value of these Industrial Exhibitions to a city like San Francisco, but it is not difficult to see many practical benefits that have resulted to the world of science, industry and art.

Dating from the exhibition of 1851, the projenitor of this style of industrial exhibition, an exemplification is the wonderful improvements made in the style of doing engineering and mechanical work, and the cultivated thought bestowed thereon.

We have always had prominent examples of excellence in design and finish in many public works entrusted to special men, but the general tone of work in all the branches of art and industry has advanced enormously since the year of the first great international exhibition, and this is due to the direct and free interchange of observation and ideas between different nations and their representative men. For example, the massiveness and simplicity of machines of English make, and lack of beauty and design, the elegance and complicacy and extreme lightness of machines of French make, have both become modified and the best of both are now found combined in each. So also in large public works, the best points of all such works, wherever constructed, have been brought before the engineering world through these industrial exhibitions, and the world has had the benefit of them.

A Stimulus to Investigation.

They have stimulated investigation, arrested thought, generated energy, broken down false pride, and through inquiries suggested by fact-developed, have liberalized the professions and have endowed the arts and industries with a value heretofore unknown.

When one wanders though the avenues of these industrial exhibition buildings, among the silent and expressive evidences of thought; through genius put in form and substance, involuntarily he wonders if man has a limit set to his work, and whether the mission of man in this age is not that of machine builder, giver of life to dead metal and energy to inanition. And it would seem when we witness the subtle motion and nervous activity of the mechanical parts of many a machine, that the Maker of all Things, through man, had imparted to them the faculty of doing what man by means of his hands can do, and requiring but the aid of his senses to give them life and being.

The ever restless spirit in man requires a channel through which his restlessness finds a counter-irritant, in the soothing influence of mental and physical occupation. The present age is favorable to invention, to commerce and economical industry, and thus preserves the man and builds up his faculties; on the other hand, if his energies were expended in war and bloodshed, or in pleasure and sensuality, invention, commerce and the economic industries would disappear and man would lapse into semi-barbarism or degenerate in effeminacy or effeteness.

Every citizen who sincerely and honestly wishes good to his country, must recognize the

THE O'HARRA
CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at $6	$12.00
Two firemen at $4	8.00
150 lbs of salt at 1½c	22.50
Wear of shoes and power	1.50
Cost for 15 tons	$44 00
Cost for one ton	2.93½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Feavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

DEETKEN'S
ROASTING FURNACE,
For Gold, Silver and Copper Ores.

The roasting capacity of the Furnace, per 24 hours, is from 6 to 50 tons, according to percentage and nature of the sulphureted ore, with an expenditure of one and a half to two cords of wood, and two to three shifts of unskilled labor, according to amount of ore handled. The Furnace is adapted for chloridizing, as well as oxidizing, roasting, and for the manufacture of sulphuric acid. In point of cheapness of construction and efficiency in working, the Furnace is far the best in use. Millmen in need of a cheap and efficient Roasting Apparatus will apply to

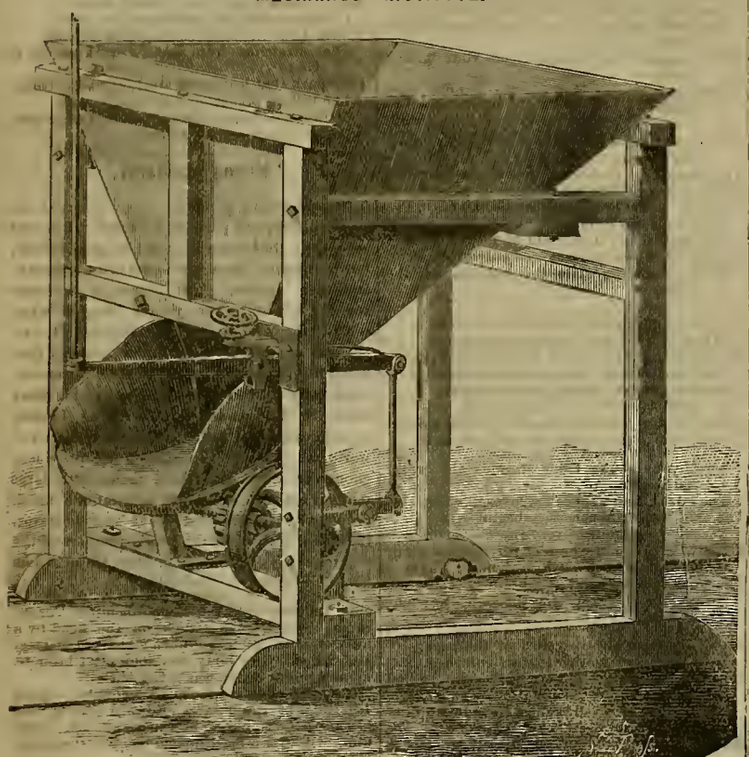
HENDY & COCHRANE'S ORE FEEDER

FOR QUARTZ MILLS,

AWARDED FIRST PREMIUM AT THE TENTH INDUSTRIAL FAIR OF THE MECHANICS' INSTITUTE.



It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the *carrier*, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane, or table, to the line of discharge, and there simply *dropped*. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says, of the Table Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."——A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them.——Two of the machines were shipped to the Bunker Hill Mill, Amador County.——Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen.——Mr. Lachman, of the Soulsby Mill, Tuolumne County, says they work splendid; could not do better.——Two of the machines were shipped to the California Company, Nevada City.——C. J. Garland, of Mosquito Gulch, Calaveras County, says: "I find them an excellent machine."——S. D. B. Stewart, Supt. Lincoln Gold Mining Company, says they are a perfect success.——C. C. Hewitt, Supt. Keystone Mining Company, says: "I can safely recommend them to all millmen."

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other machine of its class.

(Continued from Page 113.)

potential influence of industry and honesty intelligently directed. To these ends are these industrial exhibitions dedicated, and their utility includes all this and more, and when taken in connection with the influence that Mechanic Institutes impart, the results cannot be otherthan good.

It may be proper here to state that however inseparably the Mechanics' Institute and these industrial exhibitions are connected, the managers have endeavored faithfully by the distinct and seperate organization of the two bodies to hold the Mechanics' Institute free from any possibility of loss, but the sole recipient of any profit.

Twenty-one years ago last April the Mechanics' Institute was organized, and now having attained its majority it comes before you in man's estate, happy in the esteem of the good citizens of San Francisco, invites you to visit its rooms and building, and examine its library, and will be glad to have you become a member in its family of over two thousand. It possesses a valuable library of 28,000 volumes of standard works of reference and instruction, and although representing the industries and the mechanic arts, its membership is free alike to all.

Mechanics' Institutes.

Mechanics' Institutes, like industrial exhibitions, are devoted to the interests of the people and are of the people, and their managers should desire the greatest good to the greater number in all matters of public policy and private interests.

The greatest good for the average man is that he should be educated to intelligently labor with the hands that God has given him, and to respect the rights of others to do likewise; and while the brain and mind is not neglected the body should be cultivated.

Education.

And this, involving the matter of public education—the right and obligation of every citizen to receive its education from the government—brings home to the mind the inquiry that will flash across it, how far the State can justly carry its system of education in the ascending scale of special instruction. And how long will the people consent to be taxed when the school census is greater and money supply less, if the higher branches are to be forever included in the curriculum of public education?

California may well be proud of her grammar and high schools, and universities. She has done well to lay the foundations of these institutions deep and secure so that they may last for all time to come. But having once fully endowed and fairly established them, it should be left, without affecting their fundamental principles of organization, to private good will and to those who receive the special benefits of the higher education, to provide for that which the State now supplies free.

I believe that every child is entitled to a good American elementary education in the national tongue, and the State should require that every child be so educated for the good of the State and the republic. Simplicity the course of instruction, teach habits of industry, sobriety and morality, and make labor to be respected. Take care that the school tax becomes not onerous. Educate as a necessity, not as a luxury, and distribute the benefits of free tuition with a firm and impartial hand.

After 100 years of experimenting, it is time that our experience be carefully summed up, and the summing up be made in a spirit of pure patriotism and broad benevolence, and if the line can be marked where no farther the State shall go on educating, then let those in the ascending scale of diminishing numbers support the high schools, the university and such institutions across that line and which may have been already established by the State.

While the country rejoices that this glorious republic has safely passed very many dangers of social and political character, and has attained its one hundredth year, we, in California, have additional cause for gratitude in the prosperity that has attended us throughout the 26 years of our tenancy, and for the goodness of God in planting American liberty on this Pacific coast, on such prolific soil, and preserving it here; but here, where the setting sun fringes with gold the shores of our beloved country, we have, as yet, scarcely a history, we have it all in our recollection; the past is familiar to us, the present we realize, but who dares predict the future?

The Growth of San Francisco.

The bare, unpoetic facts of the growth of this city outruns poetic license and shadows the tales of fairyland.

In less than the average age of man, 3,000 miles west of the westermost commercial city of America, has sprung into existence an American city, so famed for its commercial importance, its wealth, its depending resources, natural and industrial, that no traveler or tourist can sit down, in the quiet of retiring life, and tell the tales of his traveling unless he has visited it.

Do you mourn the departed days of quietude and happy indifference of the pueblo of Yerba Buena, when the dark-eyed Spanish maiden or the contented cock-fighting Padre held court and sway, with no interruption of their quiet, except the excitement of a hull or bear tournament, and no dream of the future, except the individual future, and no suspicion of the great destiny of that pueblo?

Or do you rejoice in the transformation of thirty years and in the greatness of San Francisco, with its bustle, its business, its hulls and bears, its thousand stacks, with the countless industries rolling out in the expanding, ascending black smoke; the innumerable ships of steam and sail riding at peace in the noble bay, from all parts of the world, waiting to receive or discharge cargo; its church spires and the religious feeling that crested them; its libraries, its theaters, its hospitals, its civilization, and its Americanism that stands on this western outpost of our common country guarding its liberties like a sentinel at the gate of republican freedom.

Thoughts Suggested by the Fair.

This industrial exhibition suggests many thoughts in connection with the industrial progress of this coast. To the most casual observer there are two interests to which all others are subservient, and these interests are of such a character and extent as to attract the attention of the commercial communities of the world.

The mines have been very productive and some have yielded such wonderful wealth, the amount of which almost staggers belief.

The earth has yielded bountifully, so bountifully that it is estimated after providing sufficient breadstuff for our people, there will be left to export for other countries, over 700,000 tons, or enough to load 700 ships of 1,000 tons burden each.

Although the agricultural and mining interests predominate so greatly, other and lesser industries are taking root and thriving, and while we cannot lay claim, as yet, to the diversified industry possessed by older States, we are yearly becoming better prepared to meet our own requirements; to be independent of outside sources of supply, and to supply our neighbors.

Our trade with Australia, Mexico, Hawaiian Islands, Japan, China, British Columbia and other foreign nations is increasing, and one of the most satisfactory evidences of our commercial growth is that of the 362,327 tons of shipping arrived in this port during the first quarter of the present year, 189,660 tons, over one-half, were from domestic Pacific ports, showing a remarkable home commerce developed between the States and Territory of the Pacific side within the last 15 or 20 years.

It requires but little investigation to realize that this radical and satisfactory change in our commercial relations is due mainly to our increased facilities for manufacturing and producing, hence, if the results have been so satisfactory under the limited opportunities of the past, is it not a guarantee of prosperity and progress in the future, if these interests are legitimately nurtured and protected?

Manufacturing Industry in California.

Every new manufacturing industry permanently established here, is worth more to the State than the discovery of three of the richest gold or silver mines, for the developing and expanding of the former adds wealth to itself, but of the latter makes it poorer. Every citizen having the good of the State at heart, should encourage by means at his command the establishing of new branches of industry, and in order to provide for their maintenance, he should see to it that in the education of youth and in the social influences that surround boys and girls, industry and honest labor should occupy a post of honor.

The manufacturer, especially the small manufacturer, labors in San Francisco under very many difficulties, and his path is not always strewn with roses; his isolation creates difficulties of supply of raw material, and usually the legitimate requirements of his business, when once established, are beyond his financial ability to meet. The high rates of interest prohibiting the borrowing of money, the peculiarity of the import laws or customs, instead of protecting, often work a great hardship on him. The anomalous condition of the national and State currency is not calculated to improve the condition of the manufacturer, and the relation between silver and gold at this time is embarrassing to manufacturer and unfair to his workmen.

A Metallic Currency.

Common sense demands that there should be but one standard of value. All values are, however, relative, but the more stable that value is, the better; and it seems reasonable to accept gold, as being less liable to fluctuate, as that standard.

No effort of government, backed by the loyal sentiments of the people, succeeded in making the dollar greenback equal in value to the gold dollar. Nor is it possible to make a debased silver dollar equal in value to a gold dollar unless that is debased in the equivalent ratio.

A great commercial and manufacturing country like this should have but one currency, an honest one, with no superior and national; a currency we should be as willing to receive for custom dues as to pay out for honest debts.

With the return of metallic currency as the general circulating medium of trade, we raise the standard of the metallic industries, and recognizing the high claims of gold as representing civilization in commerce, we accord to iron its position as the great civilizer of the economic industries.

The poetry of the by-gone may be sung, the hopes of the future cherished, in vain, if honesty and industry does not sustain the present.

This nation has been especially favored during the past century. Its commerce, its industries and its natural resources have developed in an unparalleled degree. It has, in that period of time, planted liberty and civilization over more country that it ever existed in before; it has produced men and women peers of any man or woman of the time; its genius, its invention, its literature, its learning, is in sympathy with and often in advance of sister nations. It has done more to balance the minds of men and destroy the fetters of women, than all time has done before, and while we do not forget the evil among us, let us rejoice that so large a share of good has come from the seeds planted by our forefathers, and determine in this, our nation's centenary of years, to emulate their examples of simplicity, of honesty, of industry and true patriotism.

The Artisan.

The following is the poem written for the occasion and read by Mr. Frank Soule at the opening of the Mechanics' fair:

Amid this life, so full of pleasant things,
How few the number who have ever thought,
Whose apt and cunning hand it is that brings
So many beauties from rough nature wrought;
So many comforts whence true pleasure spring;
Who each invention to perfection brought,
Transforming nature's wild and rugged dress
To forms of beauty, wealth and loveliness.

Behold! around, above you, sprung and spread
These walls, yon arch, each beam and architrave,
This dome that hangs suspended overhead
The symmetry the cunning builder gave—
Spun from the brain, to such perfection led;
And roof, and wall, and arch, and hollow nave,
Give answer; so be proud of your grand trade—
"This temple the MECHANICS' hands have made."

Who reared the shrine where Christians meet for prayer,
And formed its pinnacles that tempt the sky?
Who hung St. Peter's dome as if on air
It rested, a vast arch athwart the sky?
Who built the Pyramids, and temples where
The wondrous ruins of old Memphis lie;
Or Thebes, whose palaces and columns pile
With crumbling slabs the borders of the Nile?

His varied guilds are ancient as the time
When new life and inherent beauty told
What taste required when Eden in its prime
Surrounded man with glories manifold.
Inventive genius, pristine and sublime,
As broad as nature, as creation old,
From the first garments made in Eden blooms
Down through the ages to the busy looms.

Where Lyons weaves from shrouds the worm hath spun
The silken tissues beauty loves to wear;
The skill that with necessity begun—
Necessity continues everywhere—
Finds fit expression where'er threads are spun,
Or gliding shuttles move in dances, there—
The work of busy hand and brain is seen—
'Tis the Mechanic speaks through the machine.

He speaks from out the relics of the past:
Each shaft and temple that in ruin lies
He planned and fashioned; time and legions vast,
Came and destroyed; beneath the broad, blue skies
He thought and toiled, and from the earth at last
Tower, shaft and pinnacle began to rise,
Stretched upward, calling through the middle air
The world of faith to thought and praise and prayer.

Behold yon ship! who laid her plunking keel,
And placed and clad her timbers firm and strong?
On knee and beam, and plank the workman's seal
Of skill and labor placed; and traced along
Her model, lines of beauty; guiding wheel,
And mast, and spar, and ropes, a countless throng;
Wove, made and bent her sails that hence shall be
The pinions wafting her across the sea.

Upon the ocean thus as on the land
This artisan leaves fixed his hands' impress;
He built the ships of the Armada grand,
And molds our modern ironclads no less.
Our swift propellers his clear genius planned
The waters as the land his power confess;
He builds and sends his avitors to sail,
Buoyed on the air, to buffet with the gale.

Throughout the world, and through the lapse of time
He has been moving, and improving all
From first ideas up to the sublime;
His brain and hand have answered to the call
Of Progress; wheresoe'er might genius climb
And grand invention at its bidding fall,
Minerva-like from its creative brain,
He hath not toiled, nor thought, nor wrought in vain.

Look all around, let busy fancy wing
Throughout earth's circle; call in memory's aid,
And ask what comfort life to us would bring
But for the pleasant things his art assayed?
Your taper finger, lady, wears the ring
His own, grown rough with honest toil, hath made;
'Twas the mechanic formed for you the chair;
His fingers made the "number twos" you wear.

When fields are yellow with the golden grain
Whose heads bend down like pilgrims bowed in prayer,
And crops are ripe for harvest, hill and plain
Tossed into mimic billows by the air—
Comes not the sickle, nor the scythe again—
The patent reaper's mighty power is there;
And Ceres smiles upon the skill of man,
The plodding, keen, inventive Artisan.

I tire; too numerous the guerdons he
Hath given the world, for me to cite or sing;
Of benefactors first in rank should be
His place and fame; 'tis not the rich who bring,
Their costly purchased luxuries that we
Should highest prize; give me the simplest thing
My dear friend's hand hath made; let him who will
Choose some bought *bijou* of a stranger's skill.

Let lawyers plead; let pious parsons pray;
And doctors physic those who trust their skill;
Let merchants buy and sell; and bankers lay
Their wits together how their vaults to fill,
And do them all due honor; but the bay
And laurel worthiest should crown him still
Who fills our lives with comfort planned and wrought
By skillful hands, and long and patient thought.

And so farewell my unexhausted theme;
I scarce beyond its vestibule have trod;
Within I see the Architect's grand scheme
That stretches from earth's workers up to God.
The spark that leaves the steel; the solar beam,
The rolling planet, and the lowly clod
Bide the same laws; who follows best their plan
In labor is the greatest Artisan.

Mining Accidents.

Several mining accidents have occurred recently in different parts of the coast. It would seem as if they occur in batches, periodically, for sometimes none are heard of in a month, and then a dozen will occur in a short space of a week. Few people imagine when reading the brief dispatches mentioning the accidents in mines, how much distress they bring upon the families of the poor unfortunates. By those referred to, by us this week alone, 19 children are left fatherless. Usually in such cases they are left to the cold charity of world, as few of the miners are provident enough to leave much, and those with large families are seldom able to accumulate much property. To their credit be it said, however, that in all such cases the brother miners of the victim always give freely to assist those whom his misfortune has left destitute.

On the 3d of August, William A. Scott, chief timberman in the Leopard mine, Cornucopia, Nevada, was struck on the head by a heavy bucket, knocked down a shaft of 260 feet and killed. The body was soon after brought up and the next day was given burial.

In the Oneida mine, Amador county, August 4th, one of the miners, Edward Gonig, was killed by the tumbling of a mass of rock upon him, just after a blast he had let off. He leaves a wife and six children.

Near Grass Valley, Nevada county, on the 4th instant, a fatal accident occurred in the incline shaft of the Omaha mine. As two workmen were ascending the shaft to the surface, a loose car came thundering down the incline and struck Thomas Clemo, breaking his neck and mashing his skull as well as every bone in his body. The other miner, Alfred Argall, was struck by the car in its descent on the hip and thrown flat in the gangway, which probably saved his life. The car descended 150 feet before striking them. Clemo leaves a wife and three children. The cause of the car getting loose will be the subject matter for an investigation.

On the 9th instant, William Hurd, a miner, was killed in the Ophir mine, on the Comstock, by falling between the case and the side of the shaft. He leaves a wife and ten children.

Last Monday a miner named John Smith, was killed near Folsom, in the mining claim of C. Lawson, by a cave of earth falling upon him.

It is reported from Sweetwater, Texas, that some 3,000 Indians encamped at the North Fork of the Red river, near Fort Elliott, are preparing for the war path, and the citizens of that vicinity fear a general massacre, as the troops have been sent to reinforce Crook. Orders have been given that Indians returning to Fort Reno for rations shall be disarmed.

THE House Judiciary Committee has agreed to report a joint resolution directing the Secretary of the Interior to withhold the patent from the New Idria mining company for the Panoche Grande property until Congress can make further investigation and determine whether the company or McGarraban is owner.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

FOR WEEK ENDING AUGUST 1ST, 1876.

SHEEP SHEARS.—Robert H. Anstin, Plainsburg, Cal.

SEED PLANTERS.—William T. Easterday, Watsonville, Cal.

HYDRAULIC ELEVATORS.—Joseph Perkins, S. F.

BOX NAILING MACHINE.—Geo W. Swan, S. F.

THERMOSCOPIC LUBRICATOR.—E. D. Tyne, S. F.

FEEDING AND DISCHARGING HOPPERS.—Henry J. Huttner, New Almaden, Cal.

INSIDE DIVIDERS FOR HARVESTERS.—James Moore, Pescadero, Cal.

AMALGAMATING PROCESS.—Chas. F. Secor, S. F.

COMPOSITION BEVERAGE.—Wm. A. Winder and Melville M. Shearer, San Diego, Cal.

RE-ISSUES.

HYDRAULIC JACKS.—Philip Hinkle, S. F.

TRADE MARK.

PAPER BAGS.—Blake, Robbins & Co., S. F.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

THE small-pox epidemic seems to be on the decrease in this city.

THEY are having more hot weather in New York and Philadelphia.

THE *Sumatra* will take from ns 400 Chinese panpers and 26 lepers.

THE English education bill has passed the House of Commons.

OVER 40 fisherman perished in a gale on the coast of Great Britain, last week.

THERE is great financial disorder in India owing to the recent fall in the valne of silver.

THE anm of $1,614,531 was shipped in treasnre overland by Wells, Fargo & Co., last month.

PROPERTY owners and residents of North Beach are making a determined effort to have the Selby smelting works removed from that locality.

CHARLETON & Co., of Staunton iron works, Hartlepool, England, have snspended. Liabilities, $900,000; assets snbject to realization said to be much greater.

AN eating honse is to be opened in the vicinity of the stock boards by some enterprising ladies who want the stock sharps to drink coffee instead of liquor.

MAJOR-GENERAL IRWIN MCDOWELL, the recently appointed commander of the department of the Pacific, was accorded a public reception on his arrival on Tnesday evening last.

A COLLISION occnrred on Monday night on the Somerset & Dorset railway, near Redstock, between a London train and an empty excursion train. Twelve persons were killed and 30 injured.

GOVERNOR CHENEY has asked the New Hampshire delegation in Congress, for legislation pnnishing willful interference with ocean cables. This action is owing to the numerons breaks in the direct cable.

RHEUMATISM AND GOUT are Invariably benefited by sulphur bathing. The difficulty of procuring trustworthy sulphur baths without the dangerous exposures incident to public bathing houses, has been fully met by GLENN'S INVALUABLE SULPHUR SOAP. It is sold everywhere.

Mining and Scientific Press,

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rivnl on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Millmen, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughont the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

Kearsarge Consolidated Quicksilver Mining Company.

Principal place of business, San Francisco, Cal. Location of works, Lake Mining District, Lake County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the first day of July, 1876, an assessment of fifteen cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, No. 10 Stevenson Block, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 28th day of August, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 16th day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JAMES MCHAFFEE, Secretary.

Office, Room 10, Stevenson Block, San Francisco, Cal.

Northerly Five Cent Hill Gravel Mining Company.

Location of principal place of business, San Francisco, Cal.

Notice is hereby given that at a meeting of the Directors, held on the ninth day of August, 1876, an assessment of 75 cents per share was levied upon the capital stock of the corporation, payable immediately, to the Secretary, at the office of the company, room 3, Merchants' Exchange, California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on Monday, the 11th day of September, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 28th day of September, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

WARREN BRYANT, Secretary,

Room 33, Merchants' Exchange, San Francisco, Cal.

Taylor Mill and Mining Company—Principal place of business, city and county of San Francisco. Location of works, Garden Valley Mining District.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 10th day of August, 1876, an assessment of forty (40) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at his office, No. 607 Montgomery street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 13th day of September, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the fourth day of October, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

SAM'L S MURFEY, Secretary.

Office, No. 607 Montgomery street, San Francisco, Cal.

Office of the Tintic Milling and Mining Company, San Francisco, Cal., July 14th, 1876.

The annual meeting of the stockholders of the Tintic Milling and Mining Company will be held at the office of the company, No. 310 Sansome street, San Francisco, on Monday, August 14th, 1876, at two o'clock P. M., for the election of directors for the ensuing year, and the transaction of such other business as may be brought before the stockholders. By direction of the Board of Directors.

H. CLAY MILLER, Secretary.

San Francisco, July 14th, 1876.

11th Industrial Exhibition,

Under the Auspices of the

MECHANICS' INSTITUTE.

The managers have the honor to announce that the forthcoming Exhibition will be opened to the public on

Tuesday, August 8th,

At 11 A. M., with the usual ceremonies. By the desire and co-operation of the leading citizens of San Francisco, the Exhibition will be held on a much grander scale than heretofore.

The Exhibition Building, Occupying an Area of over 214,000 Feet

Of floor room, will be completely filled with the varied products of the skill and industry of the people and of the soil. Over 700,000 persons were admitted during the last Fair. The managers intend to engage the services of the best instrumental talent of the country, so as to enable them to give unequaled

Musical Concerts Afternoon and Evening.

In every department applications for space far exceed expectations, and surpass those of former Fairs. Intending exhibitors must not delay filing their applications, otherwise they will be excluded.

The Exhibition will continue at least one month.

There will be no charge for exhibiting space.

Application for space or for information should be addressed to the Secretary of the Board of Managers, Eleventh Exhibition, 27 Post St., San Francisco, or to J. H. Gilmore, Supt., at same address.

A. S. HALLIDIE, Pres't.
J. H. OULVER, Sec'y.

Amusements.

WADE'S OPERA HOUSE, Mission Street, near Third. Open every evening with first-class Dramatic Company. Box Office open from 9 A. M. to 10 P. M. Doors open at half past seven. Commence at eight o'clock. AIMEE IN OPERA BOUFFE.

CALIFORNIA THEATER, Bush Street, above Kearny. Open every evening with the best Dramatic Company in the United States. Box office open from 9 A. M. to 10 P. M. Seats may be secured six days in advance. Doors open at half past seven. ROSE EYTINGE.

BOUND VOLUMES of the MINING AND SCIENTIFIC PRESS from Jan. 1st, 1864, are for sale at this office at $5 per volume, two volumes a year. Unbound at $3 per volume.

Iron and Machine Works.

WM. HAWKINS. T. G. CANTRELL

HAWKINS & CANTRELL,

MACHINE WORKS,

210 & 212 Beale St.,

Near Howard, - - - SAN FRANCISCO.

MANUFACTURERS OF

Steam Engines and all kinds of Mill and Mining Machinery.

Also manufacture and keep constantly on hand a supply of our

Improved Portable Hoisting Engines,

From Ten (10) to Forty (40) Horse Power.

N. B.—Jobbing and Repairing done with Dispatch.

FULTON

Foundry and Iron Works.

HINCKLEY & CO.,

MANUFACTURERS OF

STEAM ENGINES,

Quartz, Flour and Saw Mills,

Hayes' Improved Steam Pump, Brodis's Improved Crusher, Mining Pumps, Amalgamators, and all kinds of Machinery.

N. E. corner of Tehama and Fremont streets, above Howard, San Francisco.

THE RISDON

Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868.
CAPITAL.....$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,

SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, C. E. McLane,

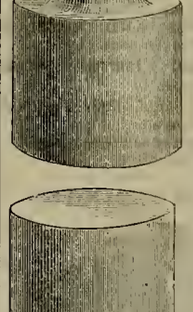
PATENTED

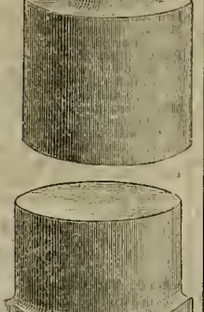
CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents to 12 Cents Per Pound.





Owing to our largely increased business, the present low price of Iron from which our Steel is manufactured and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at 12 cents per pound, delivered at San Francisco or Sacramento, instead of 16 cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc.

Address all orders, with dimensions or drawings, to

CAST STEEL SHOE & DIE CO.,
59 Nevada Block, S. F.

PACIFIC

Rolling Mill Company,

SAN FRANCISCO, CAL.

Established for the Manufacture of

RAILROAD AND OTHER IRON

—AND—

Every Variety of Shafting,

Embracing ALL SIZES of

Steamboat Shafts, Cranks, Piston and Connecting Rods, Car and Locomotive Axles and Frames,

—ALSO—

HAMMERED IRON

Of every description on hand.

☞ Orders addressed to PACIFIC ROLLING MILL COMPANY, P. O. box 2032, San Francisco, Cal., will receive prompt attention

☞ The highest price paid for Scrap Iron.

OCCIDENTAL FOUNDRY,

137 and 139 First street, - San Francisco

STEIGER & KERR,

IRON FOUNDERS.

Quicksilver Condensers and Furnace Castings.

Sole manufacturers of the Hepburn Roller Pan and Callahan Grate Bars, suitable for Burning Screenings.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

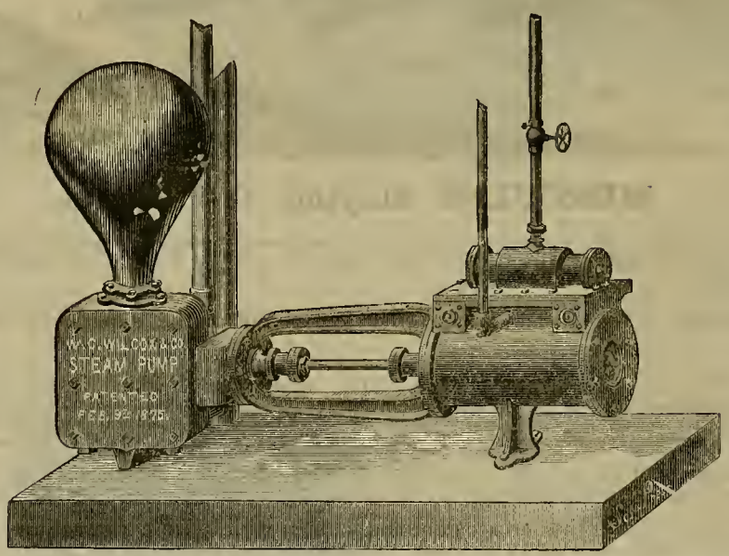
Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.



We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim.** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

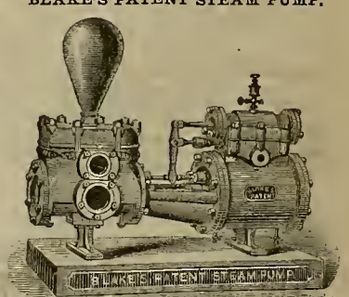
Nathan & Dreyfus' Glass Oilers, and Mill and Mining Supplies of all Kinds.

BLAKE'S PATENT STEAM PUMP.



Over 8,500 in Succeesful Use in the United Statee.

HERCULES POWDER.

HERCULES Slaying the Giants.

Hercules, the son of Jupiter and Alcmena, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion, he was sent by Eurystheus to execute very great task, when he found himself opposed by several Giants, among whom were the powerful Giant Geryon, Eurytion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by th explosion. With this powder one-half the time is saved that is lost by nsiog any other strong Powder, before you can resume work after a blast.

2. UNIFORMITY.—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.

3. SAFETY—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow tho rules laid dowo for its use. No Powder has ever heen invented where so few accidents have happened with it in proportion to the quantities which have been nsed.

4. CARTRIDGES.—It is well known that nitro-glycerine has a tendency to decompose by volitilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the oscape of these "lumes" an almost hermetically sealed cartridge is employed, and so effeotnally is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally nsed for cartridges.

5. ECONOMY.—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per oent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. {Hercules X X No. 1, for extreme hard rock. {Hercules X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself:*

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D., 1875.

Present:—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court; Honorable Lorenzo Sawyer, Circuit Judge.

THE GIANT POWDER COMPANY vs. THE CALIFORNIA POWDER WORKS, ET AL., *In Equity, No.* 1,233—The Court having, on the 22d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said hill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said hill having expired, and the default of said complainant to amend its said hill having heen duly entered, and the Court having on the sixth day of October of the said term and year, on motion of O. R. Greathouse, Esq., solicitor for defendants, M. A. Wheaton, Esq., Solicitor for complainant, heing present, in open Court, and declining to amend his said hill of complaint, he having elected to abide by his said hill of complaint as filed in this cause, ordered that a decree he entered herein dismissing said hill.

Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said hill he, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended.

October 18th, 1875.

(Signed) LORENZO SAWYER,
U. S. Circuit, Judge Ninth Circuit.

ENDORSED:—Filed and entered, October 18th, 1875.

L. S. B. SAWYER, Clerk.
By J. F. O'BERNE, Dep. Clerk.

Sold by THE CALIFORNIA POWDER WORKS, 314 California Street, San Francisco, Cal.

Also, all grades of Black Powder, Fuse, Shot, Caps, Etc.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, AUGUST 19, 1876.

VOLUME XXXIII Number 8.

Why Not?

[For the MINING AND SCIENTIFIC PRESS, by JNO. L. BOONE.]

Can any one give a sensible reason why a person who devises a new and patentable idea should not secure a patent upon it? I have ransacked the entire field of opposition without discovering a single reason that cannot be demolished by one whisk of the horse tail of common sense. Granting that all patents are not profitable, we must acknowledge that the expense of obtaining them, especially in the United States, is quite moderate, and that the chance of realizing from a patent is always worth the amount it costs to secure it; and I might state, as a rule, that the exclusive monopoly of any invention for seventeen years, (the term for which patents are granted) is worth the price of a patent whatever may be its character, unless it is based upon a foolish or incorrect theory, or is practically inoperative. I do not intend by this statement to be understood that every such patent will yield a fortune, or even an independence for its owner, but that as an investment of so much money it cannot be regarded as a bad financial transaction. Apathy, or rather a failure to properly put the patented article upon the market, and exaggerated ideas of its value, which leads to exorbitant demands from any one who might desire to purchase, are the principal causes of inventors failing to realize from their patents. Many patentees prefer to let their patents lie unintroduced rather than dispose of them at sensible prices, when often these figures would yield a fair profit. Many a good patent is buried and forgotten until it runs out and then some one, more sensible in such matters, as like as not picks up the idea, manufactures the article, puts it upon the market, and grows wealthy upon the profits.

Again, how often it is that we run across persons who regret that they did not secure patents upon their inventions or discoveries when they first made them. Many an originator of an idea has failed to secure himself by a patent when he might have done so, and has seen his ideas appropriated, and the invented device finally become a standard article of commerce and trade. As like as not the dilatory individual spends the balance of his life in useless regrets that he missed a chance for securing a competence and probably a fortune. It was a neglected opportunity not only to become rich but to enroll his name among the list of men of genius. A few such instances as these are necessary and valuable to point a moral to our tale. Their experience is a living example to other inventors, and is one of the strongest arguments to support our "Why Not?"

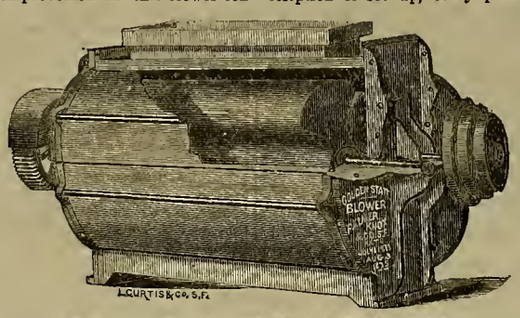
Again, leaving profit entirely out of the question, a patent is a national record of the genius of the people, and every man who can do so should be proud to have his name placed upon the record. Is it not a fact that we feel a glow of pride when we run across the name of some ancestor among the names of patentees in the patent record? We at once feel that we have inherited the national Yankee characteristic of an American, and we grow tenderer and more sympathetic with our next door neighbor who has been spending all his time and money for years in a vain endeavor to invent a perpetual motion machine. It is the only chance a great many of us may have to send our names down to posterity linked with a noble and public ambition to help ourselves and the world along. If the invention does not promise to be speedily remunerative when it is made, it should be patented nevertheless, as we do not know how soon the necessity may arise that will call for such a device. Most of the devices which the originators failed to patent and which afterwards went into general use have just such a history.

Many people are so constituted that they never pay out a dollar unless they see an immediate prospect of two dollars being returned for it. Such persons will most generally miss the main chance and have the pleasure of regretting their folly ever afterwards. I therefore ask again, *why not* patent your inventions? And I am sure every sensible person will reply "why not?"

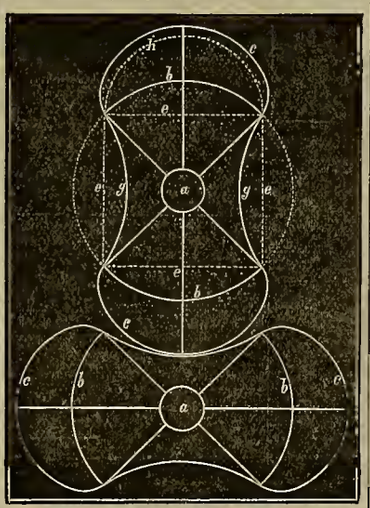
The Golden State Rotary Pressure and Suction Blower.

Among the new home inventions exhibited at the Mechanics' fair, this year, is an improved rotary pressure blower, patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Palmer & Knox, of the Golden State Iron Works, on First street, near Market. A full size blower is exhibited and also a small model one which is utilized to furnish a blast to the furnace of the Pacific Chain Works, in the machinery department. One engraving on this page gives a view of the general form of the blower and the other gives the outline of the blower wings, showing how they are made so as to form a perfect contact at all points.

The special improvement in this blower consists in constructing the arms of the two pistons or drivers upon certain peculiar curves, by which they are enabled to maintain a close fit between the circumference of the two drivers and thus utilize the machine upon blast furnaces, and on other places where a positive force is necessary to procure sufficient blast. In the construction of so called pressure blowers as heretofore made, the arcs of circles have been used to form the shapes of the drivers or pistons, and by varying the length of the chords,



THE GOLDEN STATE ROTARY BLOWER.



OUTLINE OF BLOWER'S WINGS.

while the same arcs are used for the sides, an attempt has been made to obtain a perfect fit between the two pistons at all points of their revolution. This has not been effected, however, and as a consequence, this class of blowers have been failures wherever there has been any back pressure developed. In order to overcome these difficulties Palmer & Knox construct the heads and sides of the pistons of their blower upon epicycloidal curves.

In the accompanying sketch, *a*, is the center; *b*, the pitch circle; c and *g* the epicycloid; *e e*, the chords of the pitch circle, which are equal and also form the chords of the epicycloid; *h* shows a *circle* with the same chords as the epicycloid.

In forming the heads of the pistons they make a wheel or circle the diameter of which is one-fourth the diameter of the pitch circle. Equal chords are drawn within the pitch circle, forming an exact square. The wheel or circle is placed with its tracing point upon the junction of any two of the chords and is then made to revolve once upon the outside of the pitch circle, when the tracing point will have described the epicycloid required and will stop at the point of junction of its chord and the next one. The opposite head is formed in the same manner. The sides of the pistons are traced by revolving the above mentioned wheel upon the inside of the pitch circle and upon each side between the termini of the heads, these forming a continuous circle.

It is found that when a blower of this description is set up, every point of the periphery of the two pistons exactly meet as they rotate and the fit is so perfect that the machine becomes a pressure blower capable of working against a resistence, without slip or waste. A great advantage is also found in the convenience with which the blower can be taken apart in case of need. The top quarter sections are taken off by the removal of four bolts, and the whole inside is open, so that the wings can be taken out and replaced in a few minutes.

These machines are made at the Golden State iron works in sizes from No. 1 to No. 5. The No. 5 is the size made for forges, etc., such as the one in the fair furnishing a blast to the chain works forge. No. 1 is the size exhibited near by. This latter at 125 revolutions gives 1,000 cubic feet of air. This amount can of course be increased in proportion to speed.

A peculiarity about the blower is that, as we are informed, it is the only one yet invented which has answered the purpose of a *suction* for drawing off the fumes of quicksilver furnaces. When used for this purpose the No. 1 is only run about 100 revolutions per minute. It is placed at the extreme end of the line of condensers and draws the fumes through them from the furnace, forcing at the same time the deleterious waste products of combustion off up the long chimneys away from the works. A great number of these blowers are in use in the quicksilver mines in this State for the purpose above specified. The Sulphur Banks mine has six of them and the Redington mine, nine four. They are also in use at the Ida Clayton, the Abbott and Buckeye mines, Colusa county, Etna, Cloverdale, Geyser, New Idria, Great Western, Annie Belcher, Livermore, Sunderland and many other mines.

BULLION SHIPMENTS.—We note shipments of bullion from different mines, as follows, during the past week: Northern Belle, $11,017; Ophir, $21,497.56; Comanche, $7,926.55; Leopard, $13 994; Coso Consolidated, $8,000; Arizona, $2,511.90; Justice, $18,000; Gold Run, $18,000; Tybo Consolidated, $20,786—so far on August account; General Thomas, $1,802; California, $186,892—making $675,373 so far on August account; Consolideted Virginia, $38,527 — making $139,786 on August account; Consolideted Imperial, $10,416. The July receipts of the principal producing mines were as follows; Belcher, $250,000; California, $2,062,400; Consolidated Virginia, $336,000; Justice, $60,000; Manhattan, $210,000; Ophir, $226,000; Tybo Consolidated, $76,000; Northern Belle, $70,336; Total, $3,291,166.

Facts about Peat.

[Written for the PRESS by SAMUEL PURNELL.—No. 3.]

Heating Power.

As might have been anticipated from the analyses, it has been proved that the relative heating power of dense peat, weight for weight, is about the same as air-dried wood, about half that of the best bituminous coals, and about two-thirds that of the Pacific coast liguitic coals. Light unconsensed surface peat proves to be not more than one-third as effective as good coal. Prepared according to late improved processes it gains considerably in effectiveness. Somewhat more combustible material is contained in consensed peat, weight for weight, than in the ordinary sods. The elimination of water by pressure improves the quality of peat in other respects, not the least of which is a a reduction of the relative amount of mineral matters contained in it—dissolved and carried off by the out-flowing water. A ton of air dried peat is worth as much as a ton of air dried wood, provided the quantity of ash in the former is not too great, say 10 per cent.

Peat is an admirable fuel for the Siemens gas producer. As with all fuels the heating power of peat depends on its composition; on the carbon, hydrogen, oxygen, and ash. The amount of oxygen required to consume a fuel is always a fair measure of the value of that fuel. Some lignites are so inferior, and some dense peat so good, that the latter may be fully as effective as the former. The heating power of good peat is sufficient to puddle iron. By careful experiment in Europe it was found that the calorific value of best air dried peat, containing 25 per cent. of hygroscopic water and no ash, was .47 absolute and 2,000 deg. C. hygrometric. According to Berthier, one pound of Irish peat will heat 50 pounds of water from 0 to 100 deg. C. In burning peat the grate bars should be deeper than with coal, and fresh air admitted behind the fire bridge. In an experiment at the city of Brooklyn waterworks, it was found that one pound of coal was equal to 2.24 pounds of peat in making steam. Taking the calorific value of pure carbon as 1,000, that of average bituminous coal will be about 950, while that of best peat (absolutely dry) will not be above 600, and that of ordinary air dried peat not above 450 to 500. When salt, as it is around the bay of San Francisco, peat is unfit for fuel; it will put out a fire. The flame of dry peat is long, hot, smokeless and reducing; although when containing an excess of moisture its flame may be oxidizing, which would nullify its value for some industrial purposes.

Adaptation to Metallurgy.

Peat when condensed and solid will make excellent charcoal, which from its high heating power is valuable to the smelter, and in the various other operations of metallurgy. In the iron blast furnace this charcoal produces a liquid and lively iron and a fusible slag. In Bohemia, Bavaria, France, Russia, and other countries where it has been used for years in iron blast furnaces, and for puddling and refining iron, it has always produced satisfactory results. It is quite as efficient, if not more so, than wood charcoal.

Peat yields from twenty-five to thirty-five per cent. of charcoal, according to the original quality. The methods for the carbonization of peat are nearly the same as for wood. Charring in heaps has been found most economical. In Bavaria the cost of charring is about $1.25 per ton of charcoal produced. Peat ashes contain phosphate of lime, and so a peat containing a large amount of ash may be injurious in an iron furnace by producing a cold short iron. Some peat ash contains as much as two and a half per cent. of phosphoric acid; a quantity perhaps precluding the use of such peat for iron.

GLOBE DISTRICT.—We have received several samples of ores from Globe district, Arizona, which may be examined at the editorial rooms of the PRESS, 414 Clay street, by those interested. We shall next week publish a full description of the district and its various mines.

CORRESPONDENCE.

Alpine County—Its Mines and Resources, Past, Present and Future.

[Written for the PRESS by VICTOR HARLAND.—No. 5.]

Silver Mountain District, Continued.

Before mentioning in detail the numerous lodes that exist in the immediate vicinity of the Scandinavian canyon, other than those already described, a general description of their appearance and position may be of more than passing interest, and enable the reader to more properly judge of their situation and proportionate relation with each other by the description as given. To a person unacquainted with this region, it most naturally appears strange that a

Formation

Not more than two or three miles in width should contain such a number of lodes with consistency so nearly parallel with each other. The existence of two or three parallel lodes, is of itself nothing unusual in mineral belts or formations of more than ordinary strength, but a visit to this locality will reveal to the beholder a series of lodes, 15 or 20 in number, all having a general parallel course with but little variation, unless forced aside by the abrupt contour of the mountain through which they force their way. These lodes are first encountered near the mouth of this canyon, (and nearly or quite within the limits of the town of Silver Mountain,) cross it diagonally at surprisingly regular intervals for a distance of two miles through its extreme length, and crossing the divide, we find a westerly continuation of the same series—in Alpine district—throughout the entire width of the belt, and until checked by the immense granite walls at the outer and westerly boundary.

These lodes vary in width from 18 inches to 20 feet, the ore from each, especially in the easterly series, closely approximating with the general character of all, ruby silver greatly predominating. The surrounding country is apparently a hornblende or syenitic porphyry, and the lodes, although so numerous as to give the mountains on either side the canyon the appearance of being bound together by massive ribs of quartz, and unexceptionably well defined and of great strength and continuity. Easily traceable, they rise upon one side the mountain, descending upon the other, and pass boldly across the intervening canyons with a regularity that admits of no other conclusion regarding their strength or character. Naturally, with such a

Number of Ore Veins

In close proximity to each other, there should be numerous feeders, spurs, etc., radiating from different points in the lodes and appearing as such upon the surface. Such is the case here, often appearing in sufficient number and size to have misled locators regarding their identity and character, and causing many extraneous locations to have been made before the claimants had sufficiently determined their true positions.

With the exception of the Exchequer, Lady Franklin and I. X. L. lodes, with their subordinate attachments, a greater portion of these several lodes have been, until within a late period, held by private individual possession, which accounts for any seeming lack of development they have received, other than the necessary annual expenditures upon each, and in this connection it is worthy of mention that the majority of claimants are old residents of the district who, never having lost faith in the ultimate value of their possessions, faithfully endeavor to perform the necessary labor to entitle them to the continued occupancy of their respective lodes. The Exchequer and Lady Franklin lodes appear near the north westerly extreme of the canyon, and at an altitude of 1,200 feet above the town of Silver Mountain. At a short distance below and upon two or more of these parallel lodes is situated the property of the

I. X. L. Company.

This company is of English organization, and aside from the Exchequer have expended more capital in development than any other company in the immediate vicinity.

The Acacia lode, which is credited with a subordinate existence—a part and portion of the Buckeye and probably uniting with that lode at a point below the present workings—is of smaller proportions, and although containing in places some fine looking ore, has not the ultimate value, as a mine, that is due the Exchequer or I. X. L. The latter named lode is susceptible of great value when a proper depth shall have been reached. A surface tunnel of about 500 feet was driven upon this lode in the earlier period, disclosing a body of ruby ore from which not less than $18,000 was extracted, and reduced by the common mill process then known, and which was of course partially ineffectual when applied to the reduction of this class of ores. Later, a tunnel approximating 1,000 feet in length, was driven from near the base of the mountain, following the course of the lode for a portion of the distance, and developing ore chutes of a nature and extent sufficient to inaugurate the sinking of a permanent shaft upon the property. Accordingly in 1872 or '73 a new shaft was commenced and the work progressed steadily until a depth of 200 feet was attained, the lode being intersected at this point, when, owing to financial difficulties and arrearages which had accrued, work was suspended for a time, and until the liabilities could be liquidated to the satisfaction of all.

During the past month work has again been resumed, and at present writing a good working force is employed in clearing the shaft of water, placing in position necessary machinery and preparing for the further development of the mine at this level and at greater depths below. The manager, Mr. Chalmers, being fully acquainted with the prospects of the mine, having given the former developments his personal supervision, is confident of success when sufficient depth is reached upon the lode. Its position in the shaft at the present depth and the uniform dip from the surface, together with its general appearance at these several points where encountered, proves its permanency as a lode, and it remains but a question of time when this, as well as many other valuable locations in this belt, will unfold to the public gaze their wealth, now locked up in the mysterious treasure vaults of mother earth.

This property together with that of the Exchequer company and other lodes under the supervision and control of Mr. Chalmers has lately been surveyed by U. S. Deputy L. L. Hawkins, preparatory for application for U. S. patent. With the comparative relationship which his lode bears with the Exchequer and Lady Franklin, the relative positions and dip of the ore chutes heretofore discovered, their gradually increasing proportions as depth is gained, give rise to the prediction of the presence of large bodies of milling ore, which may eventually be opened from the shaft.

The Vast Deposits

Discovered at various points on the Comstock have effectually banished the idea of a non-existence of the precious metals at great depths, the opinions of a few skeptical and self-constituted mining experts to the contrary notwithstanding. Add to this the fact that these mines with others near them and of like character, are situated at such great altitude above the immediately surrounding country, showing at various points above and beneath the surface their true nature as mineral bearing lodes, and producing at these slight depths attained unmistakable evidences of a gradual increase in size of the paying bodies, what may not reasonably be expected of them when such depths shall have been attained as are now being opened on the Comstock.

Iron and its Relations to Civilization.

The following is the oration delivered at the opening exercises of the 11th industrial exhibition of the Mechanics' institute by Henry Edwards, esq. Want of space prevented us publishing it last week:

Oration by Henry Edwards, Esq.

LADIES AND GENTLEMEN: There is a time in the life of every man when embarrassing circumstances seem almost to surround and overwhelm him, and if that time never reached me before, it would appear to have come upon me now. The kindly manner, however, in which the request of the Directors that I should make this address was conveyed to me, left me no resource but to accede to their wish, and do the best I could to fill the position which their too generous estimate of my abilities has forced upon me to-day. During some days of anxiety, when the subject on which I should speak to you chiefly occupied my thoughts, one of the warmest friends of this institution, a gentleman known and highly regarded by all, suggested to me that I should take as my theme, "Iron and its Relation to Civilization." The idea, for which I here publicly thank my friend, at once seized upon my mind, and I resolved to follow his advice, begging you to thank him more than myself for what you may hear to-day.

The field of thought covered by this suggestion is a mighty one, far too vast for the contemplation of an hour, and only on the present occasion to be regarded as the opening of the volume, leaving the wealth of its pages untouched and unexplored. It is one of the contradictions of our imperfect nature, that those objects which are always present with us, and which become, as it were, a part of our every day existence, receive too little consideration at our hands. We take them as our right, and utterly unconscious of that spirit of gratitude which should fire our souls at the knowledge of the countless blessings which are ours unsought, we pause not to consider whence they come, how important they may be to our daily wants, or how great the loss we would sustain by their withdrawal from our possession. And iron is one of these—iron, that common metal with which we are all so familiar, with the use of which, in some form or other, we hourly come in contact, of whose chemical constituents we now know much, whose formation and geologic conditions have been made clear by the light of modern science, but whose

Discovery by Man,

And his first application of the metal to the uses of his life are all but a sealed book to us, the smallest streaks of light alone breaking in upon us to relieve the darkness of our search. Far off in that remote period in which history is utterly lost, and even tradition becomes merged in the gloom of obscurity, we may imagine some dusky savage starting with delight and wonder as he views the sparkling crystals of the heavy lump of stone beneath his feet, of the composition of which he knew nothing, but which in after ages was destined to be the greatest "boon to mortals given," the grand handmaid of progressive civilization, and the all but indestructible basis of the noblest works which ever emanated from the genius of mankind. How the

First Crude Worker in Iron

Conceived the idea of reducing that coarse, heavy mass into a malleable form, rendering it plastic and obedient to the skill of his hands we know not. Here the curtain falls upon our ken, and imagination, unaided by positive knowledge, can alone assist us. Owing, however, to the difficulty which exists in reducing it from its ores, its extreme hardness and want of discrimination as to which variety of ore would be the most productive, it would appear that iron was by no means the first metal whose use was learned by our progenitors, doubtless yielding in this respect to lead, silver and copper. But still in this statement we are wandering into the realms of speculation. The condition of man in his earliest ages of existence was probably as different in all its general characters as our own may be from that of the inhabitants of Jupiter or Saturn, and the only certainty we can lean upon is, that the metal once found, its uses gradually became known, the first purposes to which it was applied being most probably the fabrication of weapons of the chase or of war. These far off times are shrouded in mystery, but as we stand awhile upon the mountain of thought, far removed from the petty vexations of life, and contemplate the stir which everywhere around us has proceeded with the most ceaseless activity, we see written as the eternal law of Providence

A Progressive Change

From a lower to a higher form of existence, and recognize in every department of our being examples of this progress working ever upward and onward to a grand purpose—a purpose ever unfulfilled, but expanding day by day and hour by hour nearer and ever nearer to that perfection which, though never absolutely reached, is yet, in the very nature of things, one day compelled to burst into the open sky of peace, of freedom and of love. And so, as the geologist by the aid of physical facts can trace the growth of worlds, and assign to each created thing his place and period in the past scale of creation from the azoic age, devoid as the name implies of the smallest trace of life, up to that marvelous epoch when the earth echoed with the tread of man—so can we understand how that mighty being

"By slow degrees, by more and more,"

Improved in growth and culture, and gave evidences, even in those barbaric days, of a civilization yet to be, a civilization yet unseen, but as perfect and as certain as is the form of the flower within the unopened beauty of the bud. And as he grew stronger and stronger, gaining hourly in intelligence, and in each century of his existence removing himself further and further from the brute condition of his primal form, fulfilling that eternal law of outgrowth which shines with untiring brilliancy upon all the handiwork of God, his wants necessarily became more and more numerous—the products of earth were searched and tested to satisfy their desires, and every object which could by any means aid those wants, was greedily seized and forced into the army of their supply. Among these, iron undoubtedly held a foremost place, and though we can assign no positive period as the date of

Its First Manufacture,

The researches of Sir John Lubbock and others marked its existence among the lacustrine dwellings of Switzerland, away back in those prehistoric times when man had no records, and has left no trace of his existence beyond the buried relics of his primitive homes. While descending the stream of more approximate history we find that Homer, who is supposed to have lived in the ninth century before Christ, is credited in Pope's translation of the *Iliad* and the *Odyssey*, with many allusions to this metal. In the latter poem Minerva, under the guise of "Mentor, monarch of the Paphian land," while explaining to Telemachus the reason of her visit to Ithaca, says:

"Freighted with iron from my native land
I steer my voyage to the Brutian strand,
To gain by commerce, from the labored mass,
A just proportion of refulgent brass."

These facts would tend to show a greater

Antiquity for the Use of Iron

Than has usually been assigned to it, and some explorations made of late years in great pyramid of Cheops, have brought to light some wedges of iron, firmly imbedded in the crevices of the enormous blocks of which these structures are composed, which could not have been manufactured, according to the best Egyptian scholars, subsequent to 3,000, B. C.; while in the buried cities of Asia and America, iron implements of various kinds and ornamental designs in the same metal have been frequently discovered. But it is from that grand storehouse of knowledge which, however degenerated to-day, has been the birthplace of many of our most treasured discoveries, from the "rich Orient, studded with her gems" that the first historical records of the uses of iron came to us, carrying us down the mighty river of time to the more familiar period of the Greek and Roman dynasties, and it is from about 300 years previous to the Christian Era that our really reliable information comes, the Romans, then the masters of the world, being probably the first to perceive the malleable properties of the metal, and to apply it to many uses before unknown. It is certain that the rich mines of the Island of Elba were worked by them upwards of 2,500 years ago, while we learn from the commentaries of Cæsar, that on his invasion of Britain, the spears and lances of the inhabitants of that island were either wholly made or tipped with iron, and during the occupation of Britain by Julius and his successors the rich mines of the Forest of Dean in Glostershire were constantly worked by the Romans, numberless cinder heaps in the grand old domain still remaining to mark the rude efforts of the conquerors to extract the coveted metal from its rebellious ore. Over many of these cinder heaps, now covered with rich soil, the product of disintegration and decomposition in the past centuries, I have wandered as a boy, and gathered lovely flowers which grew up in the crevices of those singular remains, the cinder heaps of Dean Forest being spots well known by every naturalist who has visited that region, in winter producing many rare and curious fungi, and in summer equally rare flowering plants, which in their turn were visited by insects elsewhere but seldom seen.

The Furnaces Used

By these people in smelting the ore are, in many cases, still in existence, being erected on the top of some eminence, so as to obtain the greatest force of the wind. Charcoal was used for the fires, and it is not difficult in some places to trace the remains of charcoal pits, nay even of the very trees cut down for the purpose of being converted into fuel. "The processes of extracting the iron were, however, naturally very rude and imperfect, and left so much iron in the cinders that several of the heaps in the Forest of Dean furnished the chief supply of ore to twenty furnaces for upwards of 200 years." From the time of the Romans the workmanship in iron gradually improved, and its use spread over Europe and Asia, large deposits being discovered in Sweden, Russia, Siberia, Persia, Italy, France and England.

Production of Iron.

The last named country now produces the bulk of this metal, one bed in the northeast of Yorkshire yielding for several years no less than the enormous amount of 400,000 tons per annum, while some mines in the county of Cumberland gave, in 1861, the almost incredible result of one million tons. Next to England in point of production stands the United States, and though very much of what is used is still imported from Europe, there is good reason to hope that in a few years, by increased facilities and by the exercise of enterprise and capital, the iron mines of

North America will Take the Lead.

Of all the world and in their turn supply much of the demand from the older countries across the Atlantic. The early settlers of this country, though soon becoming acquainted with the existence of metalliferous deposits, could not make them a special object of their search, as the beds of ore with which they were enabled to become acquainted were, for the most part, far removed in those days from their settlements, and were known chiefly to the Indians, who manifested a hostile feeling to the invaders of their soil. It was not until the year 1702 that a furnace for the purpose of smelting iron was erected in Plymouth county, Massachusetts, being followed, in a few years later by other such enterprises in Rhode Island and Maryland. The pig-iron thus produced was chiefly exported to Great Britain, where it was admitted free of duty, manufactured articles of iron and steel being returned in its stead. In 1771 the shipment of iron from this country to Great Britain amounted to 7,525 tons; the exportation ceasing with the war of independence, one hundred years ago. I am not here to-day to speak to you of your marvelous advances in every department of economy which tends to the

Permanence of Your Social Progress

Since that eventful period of American history in which an oppressed people rose to vindicate their rights and to trample beneath their liberated feet the shackles which had so long bound them; but I may respectfully, as an Englishman, ask you, natives of this vast and ever advancing country, to believe that, in common with myself, there are thousands in your mother land to-day who hail your "declaration of independence" as the dawn of a new era of freedom, not for yourselves alone, but for all who have felt the heel of the tyrant, and who crown your glorious work in this Centennial year with the thanksgiving and the blessing which ever spring from the depths of warm and sympathizing souls. And it is good to remark in this connection that that very declaration had in view in one of its clauses the grievances which the early settlers experienced in the harsh measures adopted by Great Britain to prohibit the erection of furnaces for the smelting of metals, the mother country having passed an act denouncing all such erections as "nuisances," fearing that the growth of such manufactories would tend to lessen her hold upon her transatlantic territory. But, happily, this overbearing tyranny is at an end forever, and by a tremendous bound, rather than by gradual growth, the Union has become the second in importance as an iron producing country, and this in the short space of a single century. I find it stated in *Gray's Physical Atlas* that, "after the close of the war, the chief supplies were again furnished by Great Britain from the lack in the United States of the capital necessary for the successful prosecution of the business. The natural advantages possessed by Great Britain, powerfully co-operated with her legislation, and as her

Rich Deposits of Iron and Coal

Were in close juxtaposition, and in localities not

(Continued on Page 126.)

MECHANICAL PROGRESS.

How to Hang a Grindstone.

There is probably no appliance of the machine shop ar manufactory to which so little attentian is paid as the grindstone, and it is very rare indeed that this useful tool is found to be in perfect order. A writer in the *Iron Age* gives the grindstone a tharaagh handling and we draw from him some useful hints on hanging.

There have been very decided improvements made over the old style of fixtures for hanging grindstones, which generally consisted of a square shaft, which was wedged into a square hole in the middle of the stone, at the imminent risk of bursting the stone when at rest, or of endangering the life of the grinder when in motion. Now, all abafts, from the smallest to the largest, are made of round iron (wrought), with a screw and nut, by means of which two cast iron plates are pressed against the sides of the stone, which is firmly held by pressure and friction, and relieving it from any tendency to burst, and adjusting it with the greatest precision. These plates are sometimes bolted to the sides of the stone, with a square shaft on which the stone is adjusted by means of screws passing through a projecting rim on the plates, but we think these holes have a tendency to weaken the stone.

Before adjusting the stone on the shaft the two sides should be made perfectly parallel, so that the flanges will bear evenly; then adjust the shaft, and if the stone does not run true the high side can be placed uppermost, and by gently unscrewing the nut and striking the stone it can be made to drop the desired distance which can be indicated by the flange. In our largest establishments the stones are turned off perfectly true outside of the shop, so as to avoid the dust which injures the machinery and by leaving a depression in the sides of the stone of the size of the flange it will run true without further labor. After being thus adjusted it should be kept true by the free use of the hacker, and should not be allowed to stand in water. A diamond carbon tool is used where great nicety is required, and the sides of the stone are painted (without the use of oil, however), in order to prevent the moisture from entering, and thereby keeping the edges square.

Why Grindstones Burst.

In olden times grindstones were always made with a square hole in the center, about six inches across, in which a square iron shaft was placed, and the stone adjusted by means of wooden wedges driven around the shaft with sufficient force to hold the stone securely in its place, and to resist the power applied to the shaft while dressing the stone off. This resistance at the edge being equal to a lever purchase of half the diameter of the stone, has a tendency to burst the stone by the pressure of the shaft in the eye of the stone, which is also frequently augmented by the swelling of the wood employed as wedges.
